They are branches in which a perennial Fungus (Acidium, Esoacuss, &c.) has obtained a hold. This Fungus stimulates the main twig to produce numerous adventitious buds, and these arise and the first places more or less abnormal in character, they are due to hyperrophy of young tissues, which may undergo profound alterations simultaneously, and occur on all parts of the plants. The injury which initiates them may be a puncture or Fungus infection—but the minute wound or other disturbance, instead of healing over normally, is frequently maintained as a permanent irritation of the cells by mycelia. These hairs, often occur in tufts, and are so coloured and arranged that they were long taken for Fungi and placed in the "genus" Erineum. Cecidia or galls arise by the hyperrophy of the subepidermal cells of a leaf, cortex, &c., which has been pierced by the oviposition of an insect, and in which the egg is deposited. The irritation set up by the hatching egg and its resulting larva appears to be the stimulus to development, not a poison or enzyme injected by the insect. The extraordinary forms, colours and textures of the true galls have always formed some of the most interesting of biological questions, for not only is there definite co-operation between the gall-forming insect and the gall-producing fungus, but it appears that the same insect may initiate galls of different kinds on different plants or organs, while different insects induce different galls on the same plant—e.g. the numerous galls on the oak—but the galls of different origins are usually and often strikingly similar in growth, structure, and nutriment to its particular larva, and often appears to be without injury to the plant. The latter fact is no doubt due to the production of an excess of plant materials over and above what is needed for the growth of the insect; the sense—technically Cecidia—are not always due to insects. The nodules on the roots of leguminous plants are induced by the presence of a tryphine organism known to do no injury to the plant. Those on turnips and other Cruciferous are due to the infection of Plasmodiophora, a dangerously parasitic Myxomecete. Nodules due to "eel-worms" (Nematodes) are produced on numerous cultivated plants, both tuberous and succulent, in groups resembling those of tomatoes, cucumbers, &c., and the only too well known Phyloxtera, which cost France and other vine-growing countries many millions sterling, is another case point. Fungi galls on leaves and stems are also known, but not commonly met with by plant pathologists. The black blistering swellings of Ultagis Maydes, the yellow swellings on nettles due to Acidium, &c., in many cases the swellings on leaves of maize, and may be termed asexual, due to Aphis cyntherea, many Utillagineae, &c. These cases are not easily distinguished superficially from the pustular outgrowth of actual mycelia and spores (stromata) of such Fungi as Nectria, Puccinia, &c. The cylinder galls of plants, due to Cylindrocladium, also be mentioned here, and the tyro may easily confound with these the layers and cushions of eggs laid on similar organs by many of gall-flies, &c., which are peculiar and individual, which no external cause has as yet been determined, and which are therefore often ascribed to internal causes of disease. Such are the cork-warts on elms, maples, &c., and the class of outgrowths known as Intumesences. Recent research points to definite external conditions of moisture, affecting the processes of respiration and transpiration, &c., as being responsible for some of these. The "scab" of potatoes is another case in point. Frost blisters are peculiar swellings due to the upgrowth of callus-tissue into cavities caused by the bursting of the superficial cortex under the action of intense cold.

Turning now to outgrowths of a woody nature, the well-known "burls" are common on elms and other trees are cases in point. They are due to some injury—e.g. bruising by a cart-wheel, insects—having started a callus on which adventitious buds arise. The origin of buds at the base of a branch, store of food-material being accumulated at the injured place, other buds arise at the base of or around the injured one. If matters are propitious to the development of these buds, then a tuft of twigs is formed, a so-called "burl," but if they are arrested at an early stage, new buds are again formed, and in larger numbers than before, and the continued repetition of these processes leads to a sort of conglomerate woody mass of fused bud-bases, not unlike the outer bulbs of a "turf." When large, and the crowded portion of woody material as it slowly grows. There are many varieties of burls, though all woody outgrowths of old trees are not to be confounded with them, e.g. the "knots" of texture and the "brags" of burrs are not to be confounded with "burls," and the woody "wicks" and "brons," with all the twigs arrested to extremely short outgrowths. Witches'-brooms are the tufted bunches of twigs found on silver fir, bitches and other trees, and often present resemblances to birds'-nests or clumps of mistletoe. It only seen from a distance.
with secondary results on organs or parts of organs, may be brought together under this heading. No sharp line can be drawn between these diseases and some of the preceding, inasmuch as it often depends on the local conditions whether necrosis is a dry-rot, or rather a kind of etiolation, and it would be found in the sense I employ the term "dry-rot," when it would come under the preceding category. The "dying back" of the twigs of trees and shrubs is a frequent case. The cortical tissues gradually turn brown, so that in the late summer and fall the leaves dry up the whole twig dies off. This may be due to frost, especially in "thin-barked" trees, and often occurs in beeches, pecan trees, or it may result from fire, by shot and, hailstones, gun-shot wounds in covers, &c., the latter of course being rare. It is the common result of fires passing along too rapidly to burn the trees; and "thin-barked" trees—hornbeam, beech, firs, &c.—make excellent subjects for this form of disease. The terminal twigs and smaller branches: the roots have here penetrated into subsoil or other unsuitable medium, or some drainage scheme has deprived them of water, &c., and a dry summer just turns the scale, the bark dries up and shrivels, and with the drying and cracking of the bark the foliage drops. The trees, however, are not killed outright, but their roots under pavement or other impervious covering do well for a time, but suddenly fail to supply the crown sufficiently with water during a dry season. 

7. Monstrosities.—A large class of cases of departure from the normal form, depending on different and often obscure causes, may be grouped together under this heading: most of them are of the same order as the malformations of Tissues and are due to decide how far they should be regarded as pathological if we insist that a disease threatens the existence of the plant, since many of these malformations—e.g., double flowers, phylloidy of floral parts, contortions and fascinations, dwarfish and stunted growths, &c.—may be transmitted in cultivation, but occur in nature without evident injury to the variety. In many cases, however, monstrosities of flowers have been shown to be due to the irritating action of minute insects or Fungi, and others are known which, although induced by causes unknown to us, and regarded as internal, would not be likely to survive in the wild condition. This subject brings the domain of pathology, however, into touch with that of variation, and discloses many opportunities for the correlation of the complete conditions which would decide in any given case how far a variation in form would be prejudicial or otherwise to the continued existence of a species. Under the head of malformations we place cases of abnormal development of several kinds, e.g., the malformations of Fungi or minute insects, the presence of unsuitable food-materials and so on, as well as cases of transformation of stamens into petals, e.g., in many genera of Primular, as well as in the case of the lady's slipper, Cypripedium, in which the stamens are turned into staminodia and otherwise distorted by mechanical obstacles; stumps by excess of food in rich soils, the attacks of minute parasites, overdose by climbing plants, &c. Leaves are especially apt to vary, and although the formation of crests, pitchers, suckers, &c., must be put down to the results of abnormal development, it is often difficult to draw the line between teratological and merely varietal phenomena. For instance, the difference between the long-stalked and small-stalked Pitcher plants is a clear case of a simple variation, but it is not quite certain whether the aggregation of leaves of many Umbelliferae or the submerged and floating leaves of an aquatic Ranunculus or Ceranna. When we come to phenomena such as proliferations, vivipary, the development of Lammas shoots, adventitious buds, epiphytic branches, and to those malformations of flowers known as peloria, phylloidy, vircense, &c., while assured that definite, and in many cases recognizable, physiological disturbances are at work, we find ourselves on the borderland between pathology and phytology, whereas in the cases last named must be examined with due regard to all the circumstances, and no generalization seems possible beyond what has been sketched. The true pathological is to be distinguished from the phenomenon of ogism, a term applied in the light of recent researches into the effects of external conditions on reproduction.

This sketch of an enormous subject shows us that the pathology of plants is a special department of the study of variations which threaten injury to the plant, and passes imperceptibly into the study of variations in general. Moreover, we have good reasons for inferring that different constellations of external causes may determine whether the internal physiological disturbances induced in a given plant shall lead to pathological and dangerous variations, or to changes which may be harmless or even advantageous to the plant concerned.

ECOLOGY OF PLANTS

Introduction.—The word ecology is derived from ακος, a house (habitat), and λέγος, a discourse. As a botanical term, ecology denotes that branch of botany which comprises the study of the relations of the individual plant, or the species, or the plant community with the habitat. Following Schröter¹ (Flahaut and Schröter, 1910 : 24), the term autecology may be used for the study of the habitat conditions in relation to the single species, and the term synecology for this study in relation to the plant community.

From the phytogeographical standpoint, ecology is frequently termed ecological plant geography. Thus Warming² (1901: i and 2)

¹ Flahaut and Schröter, Phytophysiographische Nomenclature: reports and propositions (Zurich, 1910).
subdivided plant geography into floristic plant geography and ecological plant geography. The former is concerned with the subdivision of the earth's surface into major districts characterized by a corresponding floristic taxonomy; the latter with the subdivision of these floristic districts, and with the geographical distribution (both past and present) of the various taxonomic units, such as species, genera, and families. On the other hand, ecological plant geography seeks to ascertain the distribution of plant communities, such as associations and formations, and enquires into the nature of the factors of the habitat which are related to the distribution of plants—plant forms, species, and communities. In a general way, floristic plant geography is concerned with species, ecological plant geography with vegetation. The study of the distribution of species dates back to the time of the early systematicists, the study of vegetation to the time of the early botanical travellers. Humboldt, for example, defined his view of the scope of plant geography as follows: "C'est cette science qui considère les végétaux sous les rapports de leur association locale dans les différents climats" (1807: 14).

The Habitat.—The term habitat, in its widest sense, includes all the factors of the environment which affect a plant or a plant community, though the term is frequently used to signify only some of these factors. The factors of the habitat may be grouped as follows: geographical, physical, and biological.

Geographical Factors.—Geographical position determines the particular species of plants which grow in the part of the world. This matter is bound up with the centres of origin and with the past migrations of species; and such questions are usually treated as a part of floristic plant geography. Here, therefore, floristics and geographical botany are closely related. Biological factors, other than geographical in the sense of defining the habitat, appear to exclude all geographical factors. They state that "the habitat is understood to include everything relating to the factors operative in a geographically defined locality, so far as these factors influence the present status of the plants, but these geographic and historical factors from the concept of the habitat do not appear to be either desirable or logical. Ecological Factors.—These factors are frequently divided as edaphic or soil factors and climatic factors; but there is no sharp line of demarcation between them. Edaphic factors include all those relating to the soil. The water content of the soil, its mineral content, its humus content, its temperature, and its physical characteristics, such as its depth and the size of its component particles are all edaphic factors. Climatic factors include all those relating to atmospheric temperature, rainfall, atmospheric humidity, and light and shade. A factor which is commonly referred to as the altitude factor, or exposure to winds are also climatic: such are often spoken of as physiological factors. The difficulty of sharply delimiting climatic and edaphic factors is seen in the case of temperature. Soil temperature depends partly on the direct rays of the sun, partly on the water content of the soil. Again, the temperature of the air is affected by radiation from the soil; and radiation differs in various soils.

Biological Factors.—These include the reactions of plants and animals on the habitat. Here again, no sharp boundary-line can be drawn. In one sense, the accumulation of humus and peat is a biological factor, as it is related to the work of organisms in the soil; but the occurrence or otherwise of these organisms in the soil is probably related to definite edaphic and climatic conditions. Again, the well-known action of earthworms may be said to be a biological work; but the resulting aeration of the soil causes edaphic differences; and earthworms are absent from certain soils, such as peat. The pollination of flowers and the dispersal of seeds by various animals are biological factors, but these are not necessarily imposed on the plant growth by the wind cannot be so regarded. The influence of man on plants and vegetation is also a biological factor, which is frequently disregarded, if it were a thing apart.

When the nature and effect of ecological factors have become more fully understood, it will be possible to dispense with the above artificial classification of factors, and to frame one depending on the exact nature of the factors. Such a classification is not possible in the present state of knowledge.

Ecology and Physiology.—Whilst our knowledge of the nature and effect of habitat is still in a very rudimentary condition, much progress has been made in recent years in the study of plant communities; but even here the questions involved in relating the facts of the distribution of plant communities to the factors of the habitat are very imperfectly understood. This is due to a lack of precise knowledge of the various habitat factors and also of the responses made by plants to these factors. Until much more advance has been made by ecologists in the investigation of the nature of habitat factors, and until the effect of the factors on the plants has been more closely investigated by physiologists, it will remain impossible to place ecology on a physiological basis: all that is possible at present is to give a physiological bias to certain aspects of ecological research. Obviously no more than this is possible until physiologists are able to state much more precisely than at present what is the influence of common salt on the plants of salt-mashes, of the action of calcium carbonate on plants of calcareous soils, and of the action of humous compounds on plants of fens and peat moors.

Ecological Classes.—Many attempts have been made to divide plants and plant communities into classes depending on habitat factors. One of the best known classifications on these lines is that by Warming. Warming recognized and defined four ecological classes as follows:

Hydrophytes.—These live in a watery or wet substratum, with at least 50% of water. Warming included plants of peat-bogs among his hydrophytes.

Xerophytes.—These are plants which live in very dry places, where the substratum has less than 10% of water.

Halophytes.—These are plants living in situations where the substratum contains a high proportion of sodium chloride.

Thermophytes.—These plants which live in localities which are neither specially dry nor specially wet but specially salty.

Such terms as hydrophytes, xerophytes, and halophytes had been used by plant geographers before Warming's time e.g., by Schouw; and the terms evidently supply a want felt by botanists as they have come into general use. However, the terms are incapable of exact definition, and are only useful when used in a very general way. The above classification by Warming, although it was without doubt the best ecological classification which had, at the time, been put forward, has not escaped criticism. The criticisms were directed chiefly to the inclusion of sand dune plants among halophytes, to the exclusion of halophytes from xerophytes, to the inclusion of " bog xerophytes " among hydrophytes, to the inclusion of all conifers among xerophytes, and of all deciduous trees among mesophytes, and to the group of mesophytes in general.

Schimper made a distinct advance when he distinguished between physical and physiological dryness or wetness of the soil. A soil may be physically wet; but if the plants absorb the water only with difficulty, as in a salt marsh, then the soil is, as regards plants, physiologically dry. All soils which are physically dry are also physiologically dry; and hence only the physiological dryness or wetness of soils need be considered in ecology.

Schimper used the term xerophytes to include plants which live in soils which are physiologically dry, and the term hygrophytes those which live in soils which are physiologically wet or damp. Schimper recognized that the two classes are connected by transitional forms, and that it is useless to attempt to give the matter a statistical basis. It is only in a general sense like Schimper's that such ecological terms as xerophytes have any value; and it is not possible, at least at present, to frame ecological classes, which shall have a high scientific value, on a basis of this nature. Whilst Schimper objected to the constitution of a special category, such as mesophytes, to include all plants which are neither pronounced xerophytes nor pronounced hygrophytes, he recognized the necessity of a third class in which to place those

ECOLOGY

PLANTS 761

plants which, like deciduous trees and bulbous plants, are hydrophytes during one season of the year and xerophytes during another season of the year. Such plants, which are characteristic of the great majority of the species of the central European flora, Schimper termed tropophytes.

Recently, Warming 1 (1909 : 130), assisted by Vahl, has modified his earlier classification, and adopted the following:

A. The soil (in the widest sense) is very wet, and the abundant water is available to the plant (at least in hydrophytes).

1. Hydrophytes. These include plants of the plankton, or microphytes, which float free in the water, the neuston, or microphytes which float on or are suspended in water, and of the benthos, or all aquatic plants which are fixed to the substratum.

2. Helophytes. These are marsh plants which normally have their roots in soil water but whose branches and foliage are more or less aerial. Warming admits there is no sharp limit between marsh plants and land plants; and it seems equally obvious that there is no sharp limit between some of his helophytes and some of his hydrophytes. For example, the difference between aquatic plants with floating leaves, such as the yellow water-lily (Nymphaea lutea) and those with erect leaves, such as Typha angustifolia, is probably more apparent than real. Among helophytes, Warming places plants of the reed swamp, and includes such trees as the elder (Alnus rugosulus), willows (e.g., Salix alba, S. fragilis, S. cinerea), S. aurita, cherry, and pine, when these grow in marshy places.

3. The soil is physically dry.

3. Oxyphytes. These plants, sometimes spoken of as "bog sercohyes," grow in soils which contain an abundance of free humus compounds, and include plants which grow on fens and moors.

4. Psychrophytes. These include the plants which grow on the cold soils of subnival and polar districts.

5. Halophytes. These are plants which grow on saline soils.

6. Lithophytes. These are plants which grow on "true rock," but not on the loose soil covering rock, even though this may entertain species that are very intimately associated with the rock. Still to this limitation an exception must be made in favour of the vegetation growing in cliffs and niches" (Warming, 1909 : 243).

Many Algae, lichens, and mosses are included among lithophytes, and these form the cushion vegetation (e.g., S. oppositifolia, Silene acaulis, and Gypsophila luteo-album).

7. Psammophytes. These are plants which grow on sand and gravel. Plants of this kind of the vegetation, whether in maritime or inland localities, are psammophytes, as well as plants (such as Calluna vulgaris) of dune heaths, dune "bushland" or scrub, and dune forest.

8. Chorophytes. Here are placed certain "chorophytic perennial herbs" which occur on "particular dry kinds of soil, such as limestone rocks, stiff clay, and so forth" (Warming, 1909 : 286).

9. The climate is very dry, and the properties of the soil are determined by climate.

10. Eriophytes. Under this term, are placed plants of deserts and steppes.

11. Psilophytes. Here are placed plants found in "sandy vegetation," viz. (i.) "thorny sandy vegetation," including: (a) orchard-scrub, (b) thorn-bushland and thorn-forest; (ii.) true savannah: tropical and sub-tropical savannah; (iii.) savannah-forest, including bush-forest in Africa and 'campos serrados' in Brazil" (Warming, 1909 : 265 seq.).

12. This new system of Warming's, whilst probably too involved ever to come into general use, must be taken as superseding his older one; 2 and perhaps the best course open to botanists is to select such terms as appear to be helpful, and to use the selected terms in a general kind of way and without demanding any precise definitions of them: it must also be borne in mind that the various classes are neither mutually exclusive nor of equivalent rank. From this point of view, the following terms will perhaps be the most useful:

Hydrophytes (submerged aquatic plants).-Plants whose vegetative organs live wholly in water; e.g., most Algae, many mosses, such as Fontinalis spp., and liverworts, such as Fungia manniata; a few Pteridophytes, such as Pilularia spp., Isolepis spp.; several flowering plants, such as Nymphaea, Ceratophyllum spp., Hottonia palustris, Utricularia spp., Littorella unguiculata.

Hemi-hydrophytes (swamp plants, marsh plants, &c.).-Plants whose vegetative organs are partly submerged and partly aerial; Vaucheria terrestres, Philomium fontana, Scapania undulata, Marsilia spp., Salixia natans, Azolla spp., Equisetum limosum, Typha angustifolia, Phragmites communis, Scirpus lacustris, Nymphaea lutea.

Hygrophytes.-Plants which are sub-evergreen or evergreen but not sclerophyllous, and which live in moist soils; e.g., Lastraea fluitans, Zostera marina, Plantago lanceolata, and Achillea Millefolium.

Xerophytes.-Plants which grow in very dry soils; e.g., most lichens, Ammophila (Psamma) arenaria, Elymus arenarius, Ananas comosus, Zea mays, Sedum acre, Bipinnulturn ssp., Artemisia herb-ala, ZollBiofia herkneriana.

Halophytes.-Plants which grow in very saline soils; e.g., Triglochin maritima, Salicornia spp., Zygophyllum cornutum, Aster tricolor, Artemisia maritima. It should be recognized that "a halophyte, in fact, is one form of xerophyte" (Warming, 1909 : 219).

Sclerophyllous Plants.-These are plants with evergreen leafy leaves, typical of tropics or sub-tropical regions; e.g., Quercus Suber, Hebe aquifolium, Hedera helix, Eucaleyptus Globulus, Rosmarinus officinalis. Sclerophyllous leaves are usually characteristic by entire or sub-entire margins, a thick cuticle, small and simple, rarely succulent and close-set, palisade tissue and a feeble system of air-spaces.

Hydro-sercohyes ("bog sercohyes").-Plants which live in wet, peaty soils, and which possess aerenchyma and xerophyllous leaves; e.g., Cladium Mariscus, Erophorum angustifolium, Rubus Chamaemorus, and Vaccinium Vitalis-Idaeo. The term "oxyphyte" is open to the objection that some peaty waters are alkaline, and not acidic as the term implies. Many plants of peaty soils are sclerophyllous.

Trochophytes.-Plants which are hydrophytes during some favourable part of the year and xerophytes during the rest of the year; e.g., Mesophytic tropics and shrubs, deciduous herbaceous plants with underground perennating organs, and annuals and ephemerals.

Plant Communities.-The study of plant communities (Formationstheorie or synecology) has made much progress in recent years. Even here, however, general agreement has not been reached; and the questions involved in relating the facts of the distribution of plant communities to the factors of the habitat are very imperfectly understood. Plant communities may be classified as follows:

A. A plant association is a community of definite floristic composition: it may be characterized by a single dominant species; or, on the other hand, it may be characterized by a number of principal species, and species which are also abundant, but not dominant, whilst elsewhere two or more species may share dominance. The former are pure associations, and are well illustrated by a heather moor, where Calluna vulgaris is the dominant plant. The latter are mixed associations, such as fens, where different facies are produced by the varying abundance of characteristic plants, such as Cladium Mariscus, Phragmites communis, Molinia coerulea, Calluna vulgaris, Juncus bulbosus, etc.

B. The soil is physically or physiologically dry.

1. Coniferous forest formations, e.g., of Pinus sylvestris, Picea excelsa, Abies pectinata, Larix sibirica, L. decidua.

2. Soil and climate favour the development of mesophytic formations.

4. This new system of Warming's, whilst probably too involved ever to come into general use, must be taken as superseding his older one; and perhaps the best course open to botanists is to select such terms as appear to be helpful, and to use the selected terms in a general kind of way and without demanding any precise definitions of them: it must also be borne in mind that the

1 Warming (1909, op. cit.).
2 Ibid. (1984, op. cit.).
3 See Moss, "The Fundamental Units of Vegetation: historical development of the concepts of the plant association and the plant formation." Botany School (Cambridge, 1910).
an association of Quercus sessiliflora may be referred to as a
Quercus sessiliflorae-formation. 

A plant formation is a group of associations occupying habitats which are in essentials identical with each other. Thus, associations of Agropyrum (Triticeum) funecum, of Carex arenaria, of Ammophila (Pavonia) arenaria, and of other plants occur on sand dunes: the associations are related by the general identity of the habitat conditions, namely, the physiological dryness and the loose soil; but they are separated by differences in floristic composition, especially by different dominant species, and by minor differences of the common habitat. The whole set of associations on the sand dunes constitutes a plant formation. 

The plant formation may be designated in technical language by the termination _-form_ added to a stem denoting the habitat. Thus, a sand dune formation may be termed an _Arenaria_. The associational term, in the genitive, may be added to the formational term to indicate the relationship of the formation and the association; thus, a plant association of Ammophila arenaria belonging to the plant formation of the sand dunes may be designated an _Arenaria Ammophila-arenaria_ (cf. Moss, op. cit. 1910: 43).

The question of universal names for vegetation units is bound up with that of the universality or otherwise of particular formations. Remote regions which are floristically distinct may possess associations of physically almost identical and yet not covered by different formations (Clements, 1905: 213). For example, the sand dunes of North America and those of western Europe are widely separated in geographical position and therefore in floristic composition, yet they are related by common physical factors. This relationship may be indicated by the addition of some prefix to the formational name. For example, an Arenaria in one climatic or geographical region might be termed an _a-Arenaria_ and one in a different region a _β-Arenaria_, and so on (Moss, loc. cit.).

It is, however, frequently desirable to consider such allied formations and group them. Such a group of formations may be designated a _plant formation_: and this term may be defined as a group of formations, which are characterized by common edaphic factors of the habitat, and which occur in any geographical region. Thus, different geographical or climatic regions are characterized by salt marshes. The latter all agree in their edaphic characteristics; but they differ climatically and in floristic composition. The salt marshes of a given region constitute a single plant formation: the salt marsh formations of the whole world constitute a plant federation.

Again, it is possible to arrange plant associations into groups related by a common plant form. Thus woodland associations may be classified as deciduous forest associates, coniferous forest associates, phyllopithaceous forests, &c. These, in a general way, are the "formations" of Warming, and (in part) the "climatic formations" of Schimper. Thus the various reed-swamps of the whole world constitute a "formation" in Warming's sense (1909: 187).

There is much difference of opinion among ecologists and plant geographers as to which of these points of view is the most fundamental. Among British authorities, it is now customary to adopt the position of Clements, who states (1905: 292) that "the connexion between formation and habitat is so close that any application of the term to a division greater or smaller than the habitat is both illogical and unfortunate," and that (1905: 18) "habitats are inseparable from the formations which they bear" (cf. Moss, 1910).

From the standpoint of plant communities, it is convenient to divide the earth's surface into (1) tropical districts; (2) sub-tropical and warm temperate districts; (3) temperate districts; (4) cold temperate and frigid districts.

2. _Warm Temperate and Subtropical Districts._—In subtropical and warm temperate districts, characterized by mild and rainy winters and hot and dry summers, we find two types of forests. First, there are forests of evergreen trees, with thick, leathery leaves. Such forests are known as sclerophyllous forests, and they occur in the Mediterranean region, in south-west Africa, in south and central Australia, and in Chile. In the Mediterranean district, forests of this type are usually dominated by the Cork Oak (Quercus Suber), sometimes by the Holm Oak (Q. ilex). When these forests become degenerate, the typical evergreen shrubs and trees, and sometimes also the large shrubs of the genus Malus, become the most important elements. In the Mediterranean region, evergreen and sub-tropical, the occurrence of many of the characteristic forest types of the Mediterranean and in Arctic regions, whose dominant species belong to the same genus (Pinus) and to the same plant form, renders it difficult to separate them into separate forest types.

difficult to regard "coniferous forests" as a natural ecological group. At much higher altitudes, in the south-west of the Mediterranean region, there is a species of evergreen cypress (Cupressus sempervirens), which also occurs in the Atlas Mountains. Some sclerophyllous forests of the eastern Atlas Mountains are, owing to a comparatively high rainfall, characterized by deciduous trees such as Olea europaea, Ulmus carpinifolia (auct. alga), Alnus cordata, Salix pedicellata, Prunus avium, &c.; and thus they have some elements in common with the deciduous forests of central Europe.

Any coniferous forest in sub-tropical or tropical regions is situated near the sea or in mountainous regions, and (as already stated) are characterized by winter rains. In inland localities, where precipitation is much lower, *steppe* occurs. For example, in southern Algeria, a steppe vegetation is situated on a flat tract about 3000 ft. (914 metres) high, between the southern slopes of the Tell Atlas and the northern slopes of the Saharan Atlas. The rainfall is very low; it is only averages about 10 in. (254 mm.) per annum. Here we find the plant associations of Helia or Esparto Grass (*Stipa tenacissima*) alternating with steps of Chli (*Achillea millefolium*); and each plant association extends for several miles in latitude. In the hollows of this steppe region, salt water lakes occur, known as Chotts; and on the saline soils surrounding the Chotts, a salt marsh formation occurs, with species of Salicornia, some of which are undershrubs.

Where precipitation is still lower, the scrub occurs. At Ghardaia, in south-eastern Algeria, the mean annual rainfall, from 1887 to 1892, was about 42 in. (114 mm.). In 1890, it fell as low as 2 in. (50 mm.) (Schimper, 1903, 666). At Beni Ouri and Colom, B. Boudier (1910, 143) stated that there had been no rain for about three years. Here the gravelly desert is characterized by "cushion plants," such as *Anabasis arabica*; *A. articulata,* &c., *Salicornia*, *Crassula*, *Sarcocornia,* by sphydry plants, such as *Ziziphus lotus* and *Zilla macroperis,* whereas succulent plants are rare. Both in the steppe and in the desert, small ephemeral species occur on the bare ground away from the large plants and especially in the wadies. Stepe and desert formations are of the open type.

3. Temperate Districts.—Temperate districts are characterized by forests of deciduous trees and of coniferous trees, the latter being of different kinds. In the warm temperate districts, but frequently of the same plant form. The identity of plant form of many of the conifers of both temperate and of warm temperate districts is probably a matter of phylogenetic and not of ecological import. Britain is fairly typical of the west European district. In these islands, we find forests of oak or woods of oak (*Quercus Robur* and *Q. sessilis*), birch (*Betula pendula*), asp or ash (*Fraxinus excelsior*), and of beech (*Fagus sylvatica*). In central Scotland, forests occur of *Pinus sylvestris,* and, in south-eastern England, extensive plantations and self-sown woods occur of the same species.

4. Seasonal Temperate Frigid Districts.—In the coldest portion of the north temperate zone, forests of dwarfed trees occur, and these occasionally spread into the Arctic region itself (Schimper, 1904, 665). Schimper distinguishes moss tundra, Polytrichum tundra, and lichen tundra, and the latter is characterized by *Cladonia tundra,* *Platysma tundra,* and *Alectoria heath.* Where the climate is most rigorous, rock tundra occurs (p. 685).

The types of vegetation (tropical forests, sclerophyllous forests, temperate forests, tundra, &c.) thus briefly outlined are groups of Schimper's "climatic formations." Such groups are interesting in that they are vegetation units whose physiognomy is, in a broad sense, related more to climatic than to edaphic conditions. For example, Schimper, after describing the sclerophyllous woodlands of the north-western district and of the Cape district, says: "The scrub of West and South Australia in its ecological aspect resembles so completely the other sclerophyllous formations that a description of it must seem a repetition." This resemblance, however, only has reference to the general aspect or physiognomy of the vegetation and to the plant forms; the floristic composition of the various sclerophyllous—and other physiognomically allied—associations in the various geographical districts is very different; and indeed it is true that, just as the general physiognomy of plant associations is related to climate, so their floristic composition is related to geographical position. Hence, in any cosmopolitan treatment of vegetation, a consideration of the vegetation regarded as having necessitated the detailed treatment of the flora from the standpoint of the climatic or geographical district in which they occur; and this

1 See Moss, Rankin, and Tansley, "British Woodlands." *Botany School* (Cambridge, 1910).

indeed is consistently done by Schimper. Finally, within any district of constant or fairly constant climatic conditions, it is possible to distinguish plant communities which are related chiefly to edaphic or soil conditions; and the vegetation units of these definite edaphic areas are the plant formations of some writers, and, in part, the "edaphic formations" of Schimper.

When a district like England is divided into edaphic areas, a general classification such as the following may be obtained:—

1. Physically and physiologically wet habitats, with the accompanying plant communities of rich, clay soils, and small marshes.
2. Physically wet but physiologically dry habitats, with the accompanying plant communities of fens, moors, and salt marshes.
3. Physically and physiologically dry habitats, with the accompanying plant communities of sand dunes and sandy heaths with little humus in the soil.
4. Habitats of medium wetness, with the accompanying plant communities of heathlands and grasslands. This class may be subdivided as follows:
   a. Habitats poor in mineral salts, especially calcium carbonate, often rich in acid humus compounds, and characterized by oak and birch woods, slender pastures, and heaths with much acid humus in the sand.
   b. Habitats rich in mineral salts, especially calcium carbonate, poor in acid humus compounds, and characterized by ash woods, beech woods, and calcareous pastures.

Ecological Adaptations.—It is now possible to consider the physiological and ecological adaptations of the members of plant communities in a given geographical district such as western Europe, of which England of course forms a part. In the present state of knowledge, however, this can only be done in a very meagre fashion; as the effect of habitat factors on plants is but little understood as yet either by physiologists or ecologists.

Hydrophytes and hemi-hydrophytes (aquatic plants).—Of marine hydrophytes, there are, in this country, only the grass-wracks (*Zostera marina* and *Z. nana*) among the higher plants. Even these species are sometimes left stranded by low spring tides, though the mud in which they are rooted remains saturated with sea-water. Although many plants typical of fresh water are able to grow also in brackish water, there are only a few species which appear to have developed in the latter habitats. Such species perhaps include *Ruppia maritima,* *R. spiralis,* *Zannichellia maritima,* *Z. pellucida,* *Potamogeton interruptus* (= *P. flabellatus,* and *Naias marina*). In freshwater lakes and ponds, especially if the water is stagnant, aquatic plants are abundant. Aquatic vegetation may be conveniently classified as follows:

Aquatic plants with floating leaves or fronds: *Glyceria fluitans, Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Lemma spp., Hydrocharis Morsus-ranae, Callitriche alba.*

Many of the latter species may have leaves or fronds of aquatic plants with floating leaves: *Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

Aquatic plants with floating leaves: *Nymphaea alba, N. capensis, N. nouchali, N. lotus, Callitriche stagnalis, Potamogeton polygonifolius.*

As very little experimental work has been done with regard to experimental drying in physically wet habitats, any classification such as the above must be of a tentative nature.
The ordinary laws of pollination. Heterophyll is rather common among aquatic plants, and is well seen in several aquatic species of Ranunculus, many species of Potamogeton, Sagittaria sagittifolia, Scirpus lacustris, Costaria (Nymphaea) alba, Hippeastr vulgare, and several other aquatic genera. 

Insectivorous species occur among aquatic plants; e.g. Ulvaticarua spp., which are locally abundant in peaty waters, are insectivorous. 

Xerophytes.—These plants have devices (a) for procuring water, (b) for retaining water or guarding it, or (c) for preventing excessive transpiration. These adaptations are obviously related to the physically or physiologically dry habitats in which the plants live. Plants of physically dry habitats, such as desert and arid steppes, are frequently long tap-roots which, in some cases, reach down to a subterranean water supply. The same plants have sometimes a superficial root system in addition, and are thus able to utilize immediately water which is near the surface of the ground, as Scleranthus dumosus, as Volkens1 maintains. Root-hairs give an enlarged superficial area to the roots of plants, and thus are related to the procuring of water.

The stems of some xerophytes, e.g. Cactaceous and Cuscutaceous plants, may be succulent, i.e. they have tissues in which water is stored. Some deserts, like those of Central America, are specially characterized by succulents; in other deserts, such as the Sahara, the thorns are not a prominent feature. Other xerophytes again are spinous. "Switch plants," such as Retama Retam and broom (Cytisus scoparius), have reduced leaves and some assimilating tissue in their stems; and stomata occur in grooves on the stem.

The transpiring surface of xerophytes is frequently reduced. The ordinary leaves may be small, absent, or spinous. In "cushion plants" the leaves are very small, very close together, and the low plants is evident. This condition is, of course, an adaptation which increases the transpiration, for the leaves are placed edge-wise to the incident rays of light and heat. The coriaceous leaves of "xerophyllous plants" also, to some extent, are similarly protective. In such leaves, there are a waxy cuticle, a thick epidermis, a thick hypodermis at least on the upper side of the leaf, well-developed palisade tissue, and a poorly developed system of air-spaces. Such adaptations are well seen in the leaf of the holly (Ilex aquifolium). Warming, however, states that Ilex aquifolium is unambiguously a mesophyte.1 (1909 : 135).

Halophytes, or plants which live in saline soils, have xerophytic adaptations. A considerable proportion of halophytes are succulent, and sometimes possess water-storing tissue and few intercellular spaces. Some halophytes tend to lose their succulence when cultivated in a non-saline soil, and have indeed been called allxhalophytes1. When cultivated in a saline soil; there is, it need scarcely be stated, little or no evidence that such plants are transmitted. British salt marshes furnish few instances of spiny plants, though such occur occasionally on the inland salt marshes of continental districts. Salix lutea is British, and a halophyte at least; and it is rather spiny. Warming states that "the stomata of true, succulent, littoral halophytic herbs, in cases so far investigated, are not sunken" (1909 : 221). It is possible, however, that the absence of sunken stomata, and the occurrence of some other halophytic features, are related merely to the succulent habit and not to halophytism, for succulent species often occur on non-saline soils. This is the case, e.g., with several of the Cyperaceae. 

The most interesting of all the halophytes, and the most characteristic of many sands, is in Arthrocnemum glacum. The interesting occurrence of certain halophytes and semi-halophytes on sea-shores and also on mountains is probably to be explained by the past distribution of the species involved. In some cases, much of the halophytic vegetation of the Mediterranean coast is related to the Mediterranean coast of the middle east. In other cases, these plants occur in the same distribution, as in Draisopsatula, as in D. scopetala. The effect of common salt on the metabolism of plants is not understood, though it is generally supposed that the effect of sea-water on the metabolism is decreased by cultivation in a saline soil, and that the leaves of

PLANTS

Cytology

The elementary unit of plant structure, as of animal structure, is the cell. Within it or its modifications all the vital phenomena of which living organisms can have their origin. Upon our knowledge of the cell and its functions, based upon both a study of its physiological activities, depends the ultimate solution of all the important problems of nutrition and growth, reception and conduction of stimuli, heredity, variation, sex and reproduction.

The Cell Theory.—For a general and historical account of the cell theory see Cytology. It is sufficient to note here that cells were first of all discovered in various vegetable tissues by Robert Hooke in 1665, and that Robert Brown in 1831, first of all recognized that the plant cell has a wall. He showed that all the organs of plants are built up of cells, that the plant embryo originates from a single cell, and that the physiological activities of the plant are dependent upon the individual activities of these vital units. This conception of the plant as an aggregate or colony of independent vital units governing the nutrition, growth and reproduction of the whole cannot, however, be maintained. It is true that in the cellular plants and the animal teall active units are separated by only a thin film of cytoplasm and that there is more or less highly developed differentiation of physiological activity giving rise to different tissues or groups of cells, each with a special function. The cell in such a division of labor becomes therefore as an independent unit. It is an integral part of an individual organization and as such the exercise of its functions must be governed by the organism as a whole.

General Structure and Differentiation of the Vegetable Cell.—The simplest cell forms are found in embryonic tissues, in reproductive cells and in the parenchymatous cells, found in various parts of the plant. The epidermal, conducting and strengthening tissues show on the other hand considerable modifications both in form and structure.

In the young plant the cell consists of a semifluid granular substance, called the cytoplasm, one or more nuclei, and sometimes centrosomes and plastids. Cells from different parts of a plant differ very much in their cell-contents. Young cells are full of cytoplasm, old cells generally contain a large vacuole or vacuoles, containing cell-sap, and with only a thin, almost invisible layer of cytoplasm on their walls. Chlorophyll grains, chromatophores, starch-grains and oil-globules, all of which can be distinguished either by their appearance or by chemical reagents, may also be present. Very little is known of the finer structure of the cytoplasm of a vegetable cell. It is sometimes differentiated into a clearer outer layer, of hyaloplasm, commonly called the ectoplast, and an inner granular endoplasm. In some cases, however, when submitted to a careful examination under the highest powers of the microscope, and especially when treated with reagents of various kinds, traces of a more or less definite structure in the form of a meshwork consisting of a clear homogeneous substance containing numerous minute bodies known as microsomes, the spaces being filled by a more fluid ground-substance. This structure, which is visible both in living cells and in cells treated by reagents, has been interpreted by many observers as a network of threads embedded in a homogeneous ground-substance. Bütschli, on the other hand, interprets it as a finely vacuolated fasum-structure or emulsion, comparable to that which is observed when small drops of a mixture of finely powdered potato and oil are placed in water, the vacuoles or air-bubbles being spaces filled with liquid, the more solid portion representing the mesh-work in which the microsomes are placed. Evidence is not wanting, however, that the cytoplasm must be regarded as fundamentally, a semifluid, homogeneous substance in which by its own activity, granules, vacuoles, fibrils, &c., can be formed as secondary structures. The cytoplasm is largely concerned in the formation of spindle fibres and centrosomes, and such structures as the cell membrane, cilia, or flagella, the coenocentrum, nematoplasts or eibrids and physodes are also products of its activity.

Protoplasmic Movements.—In the cells of many plants the cytoplasm frequently exhibits movements of circulation or rotation. The cells of the staminal hairs of Tradescantia virginica contain a large sap-cavity across which run, in all directions, numerous protoplasmic threads or bridges. In these, under favourable conditions, streaming movements of the cytoplasm in various directions can be observed. In other forms such as Elodea, Nittella, Chara, &c., where the cytoplasm is mainly restricted to the periphery of the sap vacuole and lining the cell wall, the streaming movement is exhibited in one direction only. In some cases both the nucleus and the chromatophores may be carried along in the rotating stream, but in others, such as Nittella, the chromatophores may move independently from the protoplasm in direct contact with the cell wall.¹

¹ Ewart. On the Physics and Physiology of Protoplasmic Streaming in Plants. (Oxford, 1903), gives an excellent account of the phenomena of protoplasmic streaming with a full discussion of the probable causes to which it is due.
in the Cyanophyceae. These substances can, however, be dissolved out in water, and the green colouring matter of the chloroplast then becomes visible. The chloroplast consists of two parts, a colourless ground substance, and a green colouring matter, which is contained either in the form of fibrils, or in more or less regular spherical masses, in the colourless ground-mass. The chloroplasts increase in number by division, which takes place in higher plants when they have attained a certain size, independent of the division of the cell. In Spirogyra and allied forms the chloroplast grows as the cell grows, and only divides when this divisions. The division in all cases takes place by constriction, or by a separation of one division from an equatorial plane. Chloroplasts are very sensitive to light and are capable in some plants of changing their position in the cell under the stimulus of a variation in the intensity of the light rays which fall upon them. In the chromatophores of many Algae and in the Liverwort Anthoceros there are present homogeneous, highly refractive, crystal-like bodies, called pyrenoids or starch-centres, which are composed of proteid substances and contained by an envelope of starch-grains. In Spirogyra the pyrenoids are distinctly connected by cytoplasmic strands to the central mass of cytoplasm, which surrounds the nucleus, and according to some observers, there is the exclusive division, followed by a splitting of the cytoplasmic strands. Those pyrenoids, which remain colourless, and serve simply as starch-formers in parts of the plant not exposed to the light, are called leucoplasts or amyloplasts. They are composed of a homogeneous proteid substance, and often contain albuminoid or proteid crystals of the same kind as those which form the pyrenoid. If exposed to light they may become converted into chloroplasts. The formation of starch may take place in any part of the leucoplast. When formed inside it, the starch-grains exhibit a concentric stratification; when formed externally in the outer layers, the stratification is eccentric, and the hilum occurs on that side farthest removed from the centre. As the starch-grains grow, the leucoplasts gradually disappear.

Chromoplasts are the yellow, orange or red colour-bodies found in some flowers and fruits. They arise either from the leucoplasts or chloroplasts. The fundamental substance or stroma is colourless and homogenous. The colour is due to the presence of xanthophyll, or carotin or both. The colouring matters are not dissolved in the stroma of the chromoplast, but exist as amorphous granules, with or without the presence of a protein crystal, or in the form of fine needle-shaped structures. The granules are most abundantly present in large numbers, which are grouped together in various ways in bundles and give the plastids their fusiform or triangular crystalline shape. Such substances occur in the flowers of a great number of plants, as Tamus communis, Asparagus, Lonicera, berries of Solanums, flowers of Calla, Coccineae, Tropaeolum, bracts of Strelitzia, &c., and in the root of the carrot. In some cases the plastid disappears and the cell-wall, which takes the yellow or red colour, in a variety of species, such as tulip, or pepe these crystals may consist of rods, thin plates, flat ribbons or spirals. Starch grains may often be seen in contact with the pigment crystals. The crystalline form appears to be due entirely to the carotin, which can be artificially crystallized from an alcohol or ether solution. In addition to the plastids, there are found in some plant-cells, e.g. in the epidermal cells of the leaf of species of Vanilla (Walker), and in the epidermis of different parts of the flower of Puncia, Ornithogalum, &c. (Zimmermann), highly refractive bodies of globular form, cristoblasts, which consist of a granular protein ground-substance containing drops of oil. They are stained dark red in dilute solution of alkaloids and form a mass.

Substances contained in the Protoplasm.—Starch may be found in the chlorophyll bodies in the form of minute granules as the first visible product of the assimilation of carbon dioxide, and it occurs in large quantities as a reserve food material in the cells of various parts of plants. It is highly probable that starch is only produced as the result of the activity of chromatophores, either in connexion with chromoplasts, chloroplasts or leucoplasts. Starch exists, in the majority of cases, in the form of granules, which are composed of stratified layers arranged around a nucleus or hilum. The stratification, which may be concentric or excentric, appears to be due to a difference in density of the various layers. The lowest layers, in which the density decreases more or less uniformly from the outside layer to the centre of hilum. The outermost, newly formed layer is composed of a more homogeneous, denser substance than the inner one, and can be distinguished in all starch-grains that are in process of development. The separate layers of the starch-grain are deposited on it by the activity of the chromatophore, and according to Meyer the grain is always surrounded by a thin layer of the chromatophore which completely separates it from the cytoplasm. The layers appear to be made up of elements which are arranged radially. These are, according to Meyer, acicular crystals, which he calls trichites. The starch grain may thus be regarded as a crystalline structure of the nature of a sphere, as it has been suggested by many observers.

The formation of the body in light, according to a secretion from the plasid (Meyer, 1895) or to a direct transformation of the protopl of the plasid (Timberlake, 1901) has not been definitely established.

Aleurone.—Aleurone is a proteid substance which occurs in seeds especially those containing oil, in the form of minute granules or large grains. It may be in the form of an albuminous cry-
parts of the nucleus depend to some extent upon their chemical constitution. The chromatin is practically identical with nuclein. This has a strong attraction for basic aniline dyes, and can usually be distinguished from other parts of the cell which are more easily coloured by acid anlines. But the staining reactions of nuclei may vary at different stages of their development; and it is probable that there is no method of staining which differentiates with certainty the various morphological constituents of the nucleus.

Our knowledge of the chemical constitution of the nucleus is due to the pioneer researches of Sir Lauder Brunton, Ploetz, Miescher, Kossel and a host of more recent investigators. Nuclein is a complex albuminoid substance containing phosphorus and iron in organic combination (Macallem). It appears to be a combination of a protein with nucleic acid. Recent researches have shown that the nucleic acid can be broken up by chemical means into a number of different compounds or bases. The results of these investigations are very confusing and seemed to show that nucleic acid is very variable in constitution, but thanks to the work of Schmickeberg and Stendel (Germany), Ivar Bang (Sweden) and Walter Jones and Levene (America), the confusion has been reduced to some sort of order, and it now seems probable that all ordinary nucleic acids yield two purine bases, adenine and guanine; two pyrimidine bases, cytosine and thymine; and a hexose carbohydrate, the identity of which is uncertain.

The Nucleus.—In the majority of plant-nuclei, both in the higher and lower plants, there is found, in addition to the chromatin network, a deeply stained spherical or slightly irregular body (sometimes more than one) called the nucleolus (fig. 2, A to D). It is often vacuolar, sometimes granular, and in other cases it is a homogeneous body with no visible structure or differentiation. The special function of this organ has been a source of controversy during the past few years, and much uncertainty still exists as to its true nature. It forms a part of the linin or plastin network of the nucleus and may become impregnated with varying quantities of chromatin stored up for use in the formation of the chromosomes and other nuclear activities. The relation of the nucleolus to the chromosomes is clearly seen in the reconstruction of the daughter nuclei after division in the cells of the root-apex of Phaseolus (fig. 1, A to F). The chromosomes (fig. 1, A) unite to form an irregular mass (fig. 1, B) out of which is evolved the nucleolus and nuclear network (figs. 1, E, F) by a fusion of the chromosomes (fig. 1, C, D).

Centrosome.—The centrosome is a minute homogeneous granule found in the cytoplasm of some cells in the neighbourhood of the nucleus. It is generally surrounded by a granular or radiating cytoplasmic substance. In plant cells its presence has been demonstrated in the Thalhiiophytes and Bryophytes. In the higher plants the structures which have been often described as the centrosome are too indefinite in their constitution to allow of this interpretation being placed upon them, and many of them are probably nothing more than granules of the fragmented nucleolus. The centrosomes in plants do not appear to be permanent organs of the cell. They are prominent during cell-division, but may disappear in the resting stage. They are more easily seen, when the nucleus is about to undergo mitosis, at the ends of the spindle, where they form the centres towards which the radiating fibres in the cytoplasm converge (see fig. 7, E G). The centrosome or centrosphere is usually regarded as the dynamic centre of the cell and a special organ of division; but its absence in many groups of plants does not lend support to this view, so far as plant-cells are concerned.

Division.—The formation of new cells is, in the case of uninucleate cells, preceded by or accompanied by the division of the nucleus. In multinucleate cells the division of the cell is independent of the division of the cell. Nuclear division may be indirect or direct, that is to say it may either be accompanied by a series of complicated changes in the nuclear structures called mitosis or karyokinesis (fig. 2), or it may take place by simple direct division, amitosis, or fragmentation. Direct division is a much less common phenomenon than was formerly supposed to be the case. It occurs most frequently in old cells, or in cells which are placed under abnormal conditions.\footnote{See Halliburton. Science Progress in the 20th Century (1909), vol. iv.}

It may also take place where rapid proliferation of the cell is going on, as in the budding of the Yeast plant. It takes place in the internodal cells of Characeae; in the old internodal cells of Tradescantia; and in various other cells which have lost their power of division. It has been shown that, in cells of Spirogyra placed under special conditions, amitotic division can be induced, and that normal mitosis is resumed when they are placed again under normal conditions. Amitosis is probably connected by a series of intermediate gradations with karyokinesis.

Mitosis.—In indirect nuclear division the nucleus undergoes a series of complicated changes, which result in an equal division of the chromatic substance between the two daughter nuclei. Four stages can be recognized. (1) Prophase.—The nucleus increases in size; the network disappears, and a much convoluted thread takes its place (fig. 2, B). The chromatin substance increases in amount; the thread stains more deeply, and in most cases presents a homogeneous appearance. This is commonly called the spirem-figure. The chromatin thread next becomes shorter and thicker, the nucleoli begin to disappear, and the thread breaks up into a number of segments—chromosomes—which vary in number in different species, but are fairly constant in the same species (fig. 2, C, D). Coincident with these changes the nuclear membrane disappears and a spindle-shaped or barrel-shaped group of threads makes its appearance in the midst of the chromosomes, the longitudinal axis of which is at right angles to the plane of the division (fig. 2, F). At each pole of this spindle figure there often occur fibres radiating in all directions into the cytoplasm, and sometimes a minute granular body, the centrosome, is also found there. (2) Metaphase.—The chromosomes pass to the equator of the spindle and become attached to the

\[\text{Mitosis.—In indirect nuclear division the nucleus undergoes a series of complicated changes, which result in an equal division of the chromatic substance between the two daughter nuclei. Four stages can be recognized. (1) Prophase.—The nucleus increases in size; the network disappears, and a much convoluted thread takes its place (fig. 2, B). The chromatin substance increases in amount; the thread stains more deeply, and in most cases presents a homogeneous appearance. This is commonly called the spirem-figure. The chromatin thread next becomes shorter and thicker, the nucleoli begin to disappear, and the thread breaks up into a number of segments—chromosomes—which vary in number in different species, but are fairly constant in the same species (fig. 2, C, D). Coincident with these changes the nuclear membrane disappears and a spindle-shaped or barrel-shaped group of threads makes its appearance in the midst of the chromosomes, the longitudinal axis of which is at right angles to the plane of the division (fig. 2, F). At each pole of this spindle figure there often occur fibres radiating in all directions into the cytoplasm, and sometimes a minute granular body, the centrosome, is also found there. (2) Metaphase.—The chromosomes pass to the equator of the spindle and become attached to the}\]
spindle-fibres in such a way that they form a radiating star-shaped figure—*Aster*—when seen from the pole of the spindle. This is called the nuclear plate (fig. 2, E, F, G, H). As they pass into this position they undergo a longitudinal splitting by which the chromatin in each chromosome becomes divided into equal halves. (3) *Anaphase.*—The longitudinal division of the chromosomes is completed by the time they have taken up their position in the nuclear plate, and the halves of the chromosomes then begin to move along the spindle-fibres to opposite poles of the spindle (fig. 2, I, J). Many observers hold the view that the chromosomes are pulled apart by the contraction of the fibres to which they are attached. (4) *Telophase.*—When they reach the poles the chromosomes group themselves again in the form of stars—*Diaster*—with spindle-fibres extending between them (fig. 2, K). The chromosomes then fuse together again to form a single thread (fig. 2, L), a nucleolus appears, a nuclear membrane is formed, and daughter nuclei are thus constituted which possess the same structure and staining reactions as the mother nucleus.

The spindle figure is probably the expression of forces which are set up in the cell for the purpose of causing the separation of the daughter chromosomes. Hartog has endeavoured to show that it can only be formed by a dual force, analogous to that of magnetism, the spindle-fibres being comparable to the lines of force in a magnetic field and possibly due to electrical differences in the cell. The spindle arises partly from the cytoplasm, partly from the nucleus, or it may be derived entirely from the nucleus—intranuclear spindle—as occurs in many of the lower plants (Fungi, &c.). The formation of the spindle begins in the prophase of division. A layer of delicate filamentous cytoplasm—kinoplasm—may collect around the nucleus, or at its poles, out of which the spindle is formed. As division proceeds the filamentous nature of this cytoplasm becomes more prominent and the threads begin either to converge towards the poles of the nucleus, to form a bipolar spindle, or may converge towards, or radiate from, several different points, to form a multipolar spindle. The wall of the nucleus breaks down, and the cytoplasmic spindle-fibres become mixed with those derived from the nuclear network. The formation of the spindle differs in details in different plants.

The significance of this complex series of changes is very largely hypothetical. It is clear, however, that an equal quantitative division and distribution of the chromatin to the daughter cells is brought about; and if, as has been suggested, the chromatin consists of minute particles or units which are the carriers of the hereditary characteristics, the nuclear division also probably results in the equal division and distribution of one half of each of these units to each daughter cell.

*Reduction Divisions* (*Melosis*).—The divisions which take place leading to the formation of the sexual cells show a reduction in the number of chromosomes to one-half. This is a necessary consequence of the fusion of two nuclei in fertilization, unless the chromosomes are to be doubled at each generation. In the vascular cryptogams and phanerogams it takes place in the spore mother cells and the reduced number is found in all the cells of the gametophyte, the full number in those of the sporophyte. We know very little of the details of reduction in the lower plants, but it probably occurs at some stage in the life history of all plants in which sexual nuclear fusion takes place. The reduction is brought about simply by the segmentation of the spirem thread into half the number of segments instead of the normal number. In order to effect this the individual chromosomes must become associated in some way, for there is no diminution in the actual amount of nuclear substance, and this leads to certain modifications in the division which are not seen in the vegetative nuclei. The two divisions of the spore mother cell in which the reduction takes place, follow each other very rapidly and are known as *Heterotype* and *Homotype* (Flemming), or according to the terminology of Farmer and Moore (1905) as the *meiotic phase.* In the heterotype division the spirem thread is divided longitudinally before the segmentation occurs (fig. 2, B), and this is preceded by a peculiar contraction of the thread around the nucleolus which has been termed *synapsis* (fig. 1, A). A second contraction may take place later, immediately preceding the segmentation of the thread. It has been suggested that synapsis may be connected with the early longitudinal splitting of the thread, or with the pairing of the chromosomes, but it is possible that it may be connected with the transference of nucleolar substance to the nuclear thread. The segments of each chromosome are usually twisted upon each other and may be much contorted (fig. 2, C, D), and appearances are observed which suggest a second longitudinal division, but which are more

![Various Stages in the Nuclear Division of the Pollen Mother-cells of Lilium.](fig. 2)
chromosomes to the daughter nuclei. The method by which this is brought about is, however, the subject of much controversy. There are two main theories: (1) that the chromosomes which finally separate are at first paired side by side (Allen, Grégoire, Bergs, Strasburger and others), and (2) that they are joined together or paired end to end (Farmer and Moore, Grégoire, Mottet and others). Good cytological evidence has been adduced in favour of both theories, but further investigation is necessary before any definite conclusion can be arrived at. The second or homotypic division which immediately follows reverts to the normal type except that the already split chromosomes at once separate to form the daughter nuclei without the intervention of a resting stage.

Cell Division.—With the exception of a few plants among the Thallophyta, which consist of a single multinucleate cell, Caulerpa, Vascularia, &c., the division of the nucleus is followed by the division of the cell either at once, in uninucleate cells, or after a certain number of nuclear divisions, in multinucleate cells. This may take place in various ways. In the higher plants, after the separation of the daughter nuclei, minute granular swellings appear, in the equatorial region, on the connecting fibres which still persist between the two nuclei, to form what is called the cell-plate. These fuse together to form a membrane (fig. 1, C, D) which splits into two layers between which the new cell-wall is laid down. In the Thallophyta the cytoplasm may be segmented by constriction, due to the inward growth of a new cell wall from the old one, as in Spirogyra and Cladophora, or by the formation of cleavage furrows in which the new cell-wall is secreted, as occurs in the formation of the spores in many Algae and Fungi. Cell budding takes place in yeast and in the formation of the conidia of Fungi.

In a few cases both among the higher and the lower plants, of which the formation of spores in the ascus is a typical example, new cells are formed by the aggregation of portions of the cytoplasm around the nuclei which become delimited from the rest of the cell contents by a membrane. This is known as free cell formation.

In Fucus and allied forms the spindle-fibres between the daughter nuclei disappear early and the new cell-wall is formed in the cytoplasm.

Cell Membrane.—The membrane which surrounds the protoplasm in the majority of plants is typically composed of cellulose, together with a number of other substances which are known as pectic compounds. Some of these have a neutral reaction, others react as feebly acids. They can be distinguished by their insolubility in cuprammonia, which dissolves cellulose, and by their behaviour towards stains, some of which stain pectic substances but not cellulose. Cellulose has an affinity for acid stains, pectic substances for basic stains. The cell-membrane may become modified by the process of lignification, suberization, cuticularization or gelatinization. In the Fungi it is usually composed of a modified form of cellulose known as fungus cellulose, which, according to Mangin, consists of callose in combination either with cellulose or pectic compounds. The growth of the cell-wall takes place by the addition of new layers to those already formed. These layers are secreted by the protoplasm by the direct apposition of substances on those already in existence; and they may go on increasing in thickness, both by apposition and by the intussusception of particles probably carried in through the protoplasmic fibres, which penetrate the cell-wall as long as the cell lives. The growth of the cell-wall is very rarely uniform. It is thickened more in some places than in others, and thus are formed the spiral, annular, and reticulate markings, as well as the pits which occur on various cells and vessels. Besides the internal or centripetal growth, some cell-walls are thickened on the outside, such as pollen grains, oospores of Fungi, cells of Peridinea, &c. This centrifugal growth must apparently take place by the activity of protoplasm external to the cell. The outer protective walls of the oospores of some Fungi are formed out of protoplasm containing numerous nuclei, which is at an early stage separated from the protoplasm of the oospore. In the Peridinea, Diatoms and Desmids, according to recent researches, the thickenings on the outer walls of the cells are due to the passage of protoplasm from the interior of the cell to the outside, through pores which are found perforating the wall on all sides.

Cell-walls may become modified by the impregnation of various substances. Woody or lignified cell-walls appear to contain substances called coniferins and vanillin, in addition to various other compounds which are imperfectly known. Lignified tissues are coloured yellow by aniline sulphate or aniline chloride, violet with phlobaphin and hydrazide acid, and characteristic reactions are also given by mixtures containing phenol, indol, skatol, thallin, sulphate, &c. (see Zimmermann's Microtechnique). Staining reagents can also be used to differentiate lignified cell-walls. Cuticularized or suberized cell-walls occur especially in those cells which give a formative function. They are impervious to water and gases. Both cuticularized and suberized membranes are insoluble in cuprammonia, and are coloured yellow or brown in a solution of chlor-iodide of zinc. It is probable that the cuticle or suberized cells do not contain any cellulose (Gislon, Wisselitch); whilst cuticularized cells are only modified in their outer layers, cellulose inner layers being still recognizable. The suberized and cuticularized cell-walls appear to contain a fatty body called suberin, and such cell-walls can be stained red by a solution of alcain, the lignified and cellulose membranes remaining unstained.

Fertilization.—The formation of the zygote or egg-cell takes place usually by the fusion of the contents of two cells, and always includes, as an essential feature, the formation of two germ nuclei. In many of the lower plants the fusing cells of the gametes are precisely similar so far as size and general appearance are concerned; and the whole contents of the two cells fuse together, cytoplasm with cytoplasm, nucleus with nucleus, nucleolus with nucleolus and plastid with plastid. The gametes may be motile (some Algae) or non-motile, as in Spirogyra, Mucor, Basidiobolus, &c. In many of the lower plants and in all higher plants there is a difference in size in the fusing cells, the male cell being the smaller. The reduction in size is due to the absence of cytoplasm, which is in some cases so small in amount that the cell consists mainly of a nucleus. In all cases of complete sexual differentiation the egg-cell is quiescent; the male cell may be motile or non-motile. In many of the Fungi the non-motile male cell or nucleus is carried by means of a fertilizing tube actually into the interior of the egg-cell, and is extruded through the apex in close proximity to the egg nucleus. In the Florideae, Lichens and Lobulobeniaceae the male cell is a non-motile spermatium, which is carried to the female organ by movements in the water. In Monoblepharis, one of the lower Fungi, in some Algae, in the Vascular Cryptogams, in Cycads (Cycads and Cycas), and in Ginkgo, an isolated genus of Gymnosperms, the male cell is a motile spermatozoid with two or more cilia. In the Algae, such as Fucus, Volvox, Oedogonium, Bulbochææ, and in the Fungus Monoblepharis, the spermatozoid is a small oval or elongate cell containing nucleus, cytoplasm and sometimes plastids. In the Characeæ, the Vascular Cryptogams, in Zamia and Cycas, and in Ginkgo, the spermatozoids are more or less highly modified cells with two or more cilia, and resemble in many respects, both in their...
PLANTS

structure and mode of formation, the spermatozoids of animals. In Characeae and Musciaceae they are of elongate spiral form, and consist of an elongate dense nucleus and a small quantity of cytoplasm. At the anterior end are attached two cilia or flagella. In the Vascular Cryptogams the structure is much the same, but a more or less spherical mass of cytoplasm remains attached to the posterior spirals, and a large number of cilia are grouped along the cytoplasmic anterior portion of the spiral. In Zamia (fig. 4, A), Cycas and Ginkgo they consist of large spherical or oval cells with a coiled band of cilia at one end, and a large nucleus which nearly fills the cell. They are carried by the pollen tube to the apex of the prothallus, where they are extruded, and by means of their cilia swim through a small quantity of liquid, contained in a slight depression to the oosphere. In the other Phanerogams the male cell, which is non-motile, is carried to the oosphere by means of a pollen tube. In the spermatozoids of Chara, Vascular Cryptogams, and in those of Cycas, Zamia and Ginkgo, the cilia arise from a centrosome-like body which is found on one side of the nucleus of the spermatozoid mother-cell. This body has been called a blepharoplast, and in the Pteridophytes, Cycads and Ginkgo it gives rise to the spiral band on which the cilia are formed. Belajeff regards it as a true centrosome; but this is doubtful, for while in some cases it appears to be connected with the division of the cell, in others it is independent of it. The egg-cell or oosphere is a large cell containing a single large nucleus, and in the green plants the rudiments of plastids. In plants with multinucleate cells, such as Albugo, Peronospora and Vaucheria, it is usually a uninucleate cell differentiated by separation of the nuclei from a multinucleate cell, but in Albigo blitii it is multinucleate, and in Sphaeroplea it may contain more than one nucleus. In some cases the region where the penetration of the male organ takes place is indicated on the oosphere by a hyaline receptive spot (Oedogonium, Vaucheria, &c.), or by a receptive papilla consisting of hyaline cytoplasm (Peronospora). Fertilization is effected by the union of two nuclei in all those cases which have been carefully investigated. Even in the multinucleate oosphere of Albigo blitii the nuclei fuse in pairs; and in the oospheres of Sphaeroplea, which may contain more than one nucleus, the egg nucleus is formed by the fusion of one only of these with the spermatozoid nucleus (Klebahn). In the higher Fungi nuclear fusions take place in basidia or asci which involve the union of two (fig. 7, A) nuclei, which may be regarded as physiologically equivalent to a sexual fusion. The union of the germ nuclei has now been observed in all the main groups of Angiosperms, Gymnosperms, Ferns, Mosses, Algae and Fungi, and presents a striking resemblance in all. In nearly all cases the nuclei appear to fuse in the resting stage (fig. 5, C). In many Gymnosperms the male nucleus penetrates the female nucleus before fusing with it (Blackman, Ikene). In other cases the two nuclei place themselves side by side, the nuclear membrane between them disappears, and the contents fuse together—nuclear thread with nuclear thread, and nucleolus with nucleolus—so completely that the separate constituents of the nuclei are not visible. It was at one time thought that the centrosomes played an important part in the fertilization of plants, but recent researches seem to indicate that this is not so. Even in those cases where the centrosome, which is the product of the centrosome-like body or blepharoplast, enters the ovum, as in Zamia (c in fig. 4, B, C, D), it appears to take no part in the fertilization. The phenomena, nor in the subsequent division of the nucleus. During the process of fertilization in the Angiosperms it has been shown by the researches of Navaschin and Guignard that in Lilium and Frillitaria both generative nuclei enter the embryo sac, one fusing with the oosperm nucleus, the other with the polar nuclei (fig. 3, A, B). A double fertilization thus takes place. Both nuclei are elongated vermiciform structures, and as they enter the embryo sac present a twisted appearance like a spermatozoid without cilia (fig. 3, A, B). It has since been shown by other observers that this double fertilization occurs in many other Angiosperms, both Diocotyledons and Monocotyledons, so that it is probably of general occurrence throughout the group (see Angiosperms).

The Nucleus in Relation to Heredity.—There is a certain amount of cytological evidence to show that the nucleus is largely concerned with the transmission of hereditary characters. Whether this is entirely confined to the nucleus is, however, not certain. The strongest direct evidence seems to be that the nuclear substances are the only parts of the cells which are always equivalent in quantity, and that in the higher plants and animals the male organ or spermatozoid is composed almost entirely of the nucleus, and that the male nucleus is carried into the female cell without a particle of cytoplasm.\(^1\)

Since, however, the nucleus of the female cell is always accompanied by a larger or smaller quantity of cytoplasm, and that in a large majority of the power plants and animals the male cell also contains cytoplasm, it cannot yet be definitely stated that the cytoplasm does not play some part in the process. On the other hand, the complex structure of the nucleus with its separate units, the chromosomes, and possibly even smaller units represented by the chromatin granules, and the means taken through the complex phenomena of mitosis to ensure that an exact and equal division of the chromosomes shall take place, emphasizes the importance of the nucleus in heredity. Further, it is only in the nucleus and in its chromosomes that we have any visible evidence to account for the Mendelian character of the inheritance of characters in hybrids which are known to occur. Visible differences in the chromosomes have even been observed, especially in insects, which are due apparently to an unequal division by which an additional or accessory chromosome is produced, or in some cases one or two extra chromosomes which differ in size from the others. These differences indicate a separation of different elements in the formation of the chromosomes and have been definitely associated with the determination of sex. It is possible, however, that the segregation of characters in the gametes may depend upon something far more subtle and elusive than the chromosomes or even of possible combinations of units within the chromosomes, but so far as we can see at present these are the only structures in the cell with which it can be satisfactorily associated. Boveri in fact has put forward the view that the chromosomes are elementary units which maintain an organic continuity and independent existence in the cell. The cytological evidence for this appears to be made stronger for animal than for plant cells. From numerous investigations which have been made to trace the chromosomes through the various stages of the nuclear ontogeny of plant cells, it appears that the individuality and continuity of the chromosomes can only be conceived as possible if we assume the existence of something like chromosome centres in the resting nucleus around which the chromosomes become organized for purposes of division. Rosenberg (1909) adds evidence for

\(^1\) Strasburger (1909) states very definitely that he has observed the entrance of the male nucleus into the egg without a trace of cytoplasm.
of division, chromosomes, nuclear spindle and centrosomes are to be seen (fig. 7, C-G). The investigations of Dangeard, Harper, Blackman, Miss Fraser and many others have also

In the Cyanophyceae the contents of the cell are differentiated into a central colourless region, and a peripheral layer containing the chlorophyll and other colouring matters together with granules of a reserve substance called cyanophycin. Chromatin is contained in the central part together with granules known as volutin, the function of which is unknown. The central body probably plays the part of a nucleus and some observers consider that it has the characters of a typical nucleus with mitotic division. But this is very doubtful. The central body seems to consist merely of a spongy mass of slightly stainable substance, more or less impregnated with chromatin, which divides by constriction. At a certain stage in the division figures are produced resembling a mitotic phase (fig. 8, 1), which are not, in the opinion of the writer, to be interpreted as a true mitosis. It is interesting to note that in many species the formation of new cell-walls is initiated before any indication of nuclear division is to be seen.

The bacteria, in most cases, have no definite nucleus or central body. The chromatin is distributed throughout the cytoplasm in the form of granules which may be regarded as a distributed nucleus corresponding to what Hertwig has designated, in protozoa, chromidia.

In the yeast cell the nucleus is represented by a homogenous granule, probably of a nucleolar nature, surrounded and perhaps to some extent impregnated by chromatin and closely connected with a vacuole which often has chromatin at its periphery, and contains one or more volutin granules which appear to consist of nucleic acid in combination with an unknown base. Some observers consider that the yeast nucleus possesses a typical nuclear structure, and exhibits division by mitosis, but the evidence for this is not very satisfactory.

Tissues.—The component parts of the tissues of which plants are composed may consist of but slightly modified cells with copious protoplasmic contents, or of cells which have been modified in various ways to perform their several functions. In some the protoplasmic contents may persist, in others they disappear. The formation of the conducting tubes or secretory sacks which occur in all parts of the higher plants is due either to the elongation of single cells or to the fusion of cells together in rows by the absorption of the cell-walls separating them. Such cell-fusions may be partial or complete. Cases of complete fusion occur in the formation of laticiferous vessels, and in the spiral, annular and reticulate vessels of the xylem. Incomplete fusion occurs in sieve tubes. Tubes formed by the elongation of single cells are found in bast fibres, tracheides, and especially in laticiferous cells.

Laticiferous Tissue.—The laticiferous tissue consists of a network of branching or anastomosing tubes which contain a coagulable fluid known as latex. These tubes penetrate to all parts of the plant and occur in all parts of the root, stem and leaves. A protoplasmic lining is found on their walls which contains nuclei. The walls are pitted, and protoplasmic connexions between the laticiferous tubes and neighbouring parenchyma-cells have been seen. There are two types of laticiferous tissue—non-articulate and articulate. The non-articulate type occurs in Euphorbiaceae, Urticaceae, Asclepiadaceae, consists of long tubes, equivalent to single multicellular cells, which ramify in all directions throughout the plant. Laticiferous vessels arise by the coalescence of the simple unbranched cells. The cells not only fuse together in longitudinal and transverse rows, but put out transverse projections, which fuse with others of a similar nature, and thus form an anastomosing network of tubes which extends to all parts of the plant. The remains of the laticiferous tissue in the Compositae (Glechoma), Campanulaceae, Papaveraceae, Lobeliaceae, Papayaceae, in some Araceae and Musaceae, and in Euphorbiaceae (Manihot, Hevea). The nuclei of the original cells persist in the protoplasmic membrane. The presence of nuclei is distinguishable from cells derived from the laticiferous vessels and tubes; they can be distinguished in many cases in the young embryo while still in the dry seed (Scott), but the latex vessels in process of formation are more easily seen when germination has begun. In the process of cell-wall formation the cell-walls may undergo gradual or even complete dissolution at some point. The opening, which is at first very small, increases in size, and before the cross-wall has entirely disappeared the contents of the two cells become continuous (Scott). The absorption of the cell-walls takes place very early in the germinating seedling. sieve tubes.—The sieve tubes consist of partially fused rows of cells, the transverse or lateral walls being perforated by minute openings, through which the contents of the cells are connected with each other, and which after a certain time become closed by the formation of callus on the sieve plates. The sieve tubes contain a thin lining layer of protoplasm on their walls, but no nuclei, and the cell sap contains aminous substances which are coagulable by heat. Starch grains are sometimes present. In close contact with the segments of the sieve tubes are companion cells which communicate with the sieve tubes by delicate protoplasmic strands; they can be distinguished from ordinary parenchymatous cells by their small size and dense protoplasm. Companion cells are not found in the Pteridophyta and Gymnosperms. In the latter their place is taken by certain cells of the medullary rays and bast parenchyma. The companion cells are cut off from the same cells as those which unite to form the sieve tube. The mode of formation of the sieve plate is not certainly known; but from the fact that delicate connecting threads occur between the cells from their first development it is probable that it is a special case of the normal protoplasmic continuity, the sieve pores being produced by a second generation of the sieve-tube elements through which these delicate strands pass. According to Leconte, the young wall consists partly of cellulose and partly of a substance which is not cellulose, the latter existing in the form of slight depressions, which mark the position of the future pores. As the sieve plate grows these non-cellulose regions swell and gradually become converted into the same kind of mucous substance as that contained in the tube; the two cells are thus placed in open communication. If this is correct it is easy to see that the changes which take place may be initiated by the original delicate protoplasmic strands which pass through the cell-wall. (For further information regarding tissues, see the section on Anatomy above.)

Protoplasmic Continuity.—Except in the unicellular plants the cell is not an independent unit. Apart from their dependence in various ways upon neighbouring cells, the protoplasm of all plants is probably connected together by fine strands of protoplasm which pass through the cell-wall (Tangl, Rossow, Gardiner, Kienitz-Gerloff and others) (fig. 9). In Pinus the presence of connecting threads has recently been demonstrated throughout all the tissues of the plant. These protoplasmic strands are, except in the case of sieve tubes, so delicate that special methods have to be employed to make them visible. The basis of these methods consists in causing a partial opening of the cell-walls by dissolving in them sulphuric acid or zinc chloride, and subsequent staining with Hoffmann’s blue or other aniline dyes. The results so far obtained show that the connecting threads may be either “pit-threads” which traverse the closing membrane of the pits in the cell-walls (fig. 9, B), or “wall-threads” which are present in the wall of the cell (fig. 9, A). Both

**Fig. 9.—Continuity of protoplasm of cells of Tamus communis (A) and endosperm of Lilium martagon (B).**

pit-threads and wall-threads may occur in the same cell, but more often the threads are limited to the pits. The pit-threads are larger and stain more readily than the wall-threads. The threads vary in size and form in different plants. They are very thick in *Viscum album*, and are well seen in *Phaseolus vulgaris* and *Lilium Martagon*. They are present from the beginning of the development of the cell-wall, and arise from the spindle fibres, all of which may be continued as connecting threads (endosperm of *Tamus communis*), or part of them may be overlaid by cellulosic lamellae (endosperm of *Lilium Martagon*), or they may be all overlaid as in pollen mother-cells and pollen grains of *Helleborus foetidus*.

The presence of these threads between all the cells of the plant shows that the plant body must be regarded as a connected whole; the threads themselves probably play an important part in the growth of the cell-wall, the conduction of food and water, the process of secretion and the transmission of impulses.

**Literature.**—The following is a list of a few of the most important papers in which further information and a more complete list of literature will be found: Allen, "Nuclear Division in the Pollen Mother-cells of Lilium canadense," *Annals of Botany* (1905), vol. xxii.; Efron, "Endospermulch in the sporogenese vegetale," *La Cellule* (1904), vol. xxiii.; Blackman, "On the Fertilization, Alteration of Generations, and General Cytotherapy of the Uredineae," *Ann. of Bot.* (1904), vol. xvii.; Bütschli, *Ueber die Struktur und des Losgelöstes von Plasma und des Plasma* (Leipzig, 1892); Eng. transl. by Minchin, London, 1894; and also *Untersuchungen über Struktur* (Leipzig, 1898); Courchet, "Recherches sur les Chloroplastes," *Bot. Ann. d. sci. vol. (bot.)* (1888); Deluge, *L'Annele biaurique* (1898); the first and third forms of this work were issued from the Botanischen Institut, Berlin, for wissensch. Botanik (1897), vol. 30; Wagner, "On Nuclear Division in the Hymenocallis," *Ann. of Bot.* (1910); Wolff, "The Structure and Reproduction of Cystopus Anthropis," *Ann. of Bot.* (1910); (Theoria Plantarum, Buch 1897/1898); and further papers on this subject by Wolters, *Les Resultats de l'Année Botanique*; and Delage, *La Cellule*, *Zellen*, and Histologie et Communication,* Proc. Roy. Soc. (1905), xxvii.; and Papers of the same kind by Minchin, London, 1894, and others. It is clear that the plant body is a connected whole, and that all parts of the plant develop in parallel, and can be seen as a connected system, with the cell threads playing an important role in this development.

**Morphology of Plants.**

The term morphology, which was introduced into science by Goethe (1817), designates, in the first place, the study of the form and composition of the body and of the parts of which the body may consist; secondly, the relations of the parts of the same body; thirdly, the comparison of the bodies or parts of the bodies of plants of different kinds; fourthly, the study of the development of the parts of the body (phylogeny); fifthly, the investigation of the historical origin and descent of the body and its parts (phylogeny); and, lastly, the consideration of the relation of the parts of the body to their various functions, a study that is known as organography.

It is this last department of morphology that was the first to be pursued. The earliest scientific result of the study of plants was the recognition of the fact that the various parts of the body are associated with the performance of different kinds of physiological work; that they are, in fact, organs discharging special functions. The origin of the organography of the present day may be traced back to Aristotle, who described the parts of plants as "organs, though very simple ones." It was not until many centuries had passed that the parts began to be regarded from the point of view of their essential nature and of their mutual relations; that is, morphologically instead of organographically. Joachim Jung, in his *Isagoge phytoscopica* (1678), recognized that the plant-body consists of certain definite members, root, stem and leaf, and defined them by their different form and by their mutual relations. This point of view was further developed in the following century by Caspar Friedrich Wolf (*Theoria generationis*, 1759), who first followed the development of the members at the growing-point of the stem. He observed that the "appendicular organs," as he called the leaves, are developed in the same way, whether they be foliage-leaves, or parts of the flower, and stated his conclusions thus: "In the entire plant, whose parts we wonder at as being, at the first glance, so extraordinarily diverse, I finally perceive and recognize nothing beyond leaves and stem (for the root may be regarded as a stem). Consequently all parts of the plant, except the stem, are modified leaves." Similar views were arrived at by Goethe, though by the deductive rather than the inductive method, and were propounded in his famous pamphlet, *Versuch die Metamorphose der Pflanzen zu erklären* (1790), from which the following is extracted: "The underlying relationship between the various external parts of the plant, such as the leaves, the calyx, the corolla, the stamens, which develop one after the other and, as it were, out of one another, has long been generally recognized by investigators, and has in fact been specially studied; and the operation by which one and the same organ presents itself to us in various forms has been termed Metamorphosis of Plants."

**Pure Morphology.**—Thus it became apparent that the many
and various organs of plants are, for the most part, different forms of a small number of members of the body, which have been distinguished as follows, without any reference to function. The thallus (thallome) is a plant-body which is not differentiated into the members root, stem and leaf; it is the morphologically simplest body, such as is of common occurrence in the lower plants (e.g. Thallophyta). In a differentiated body the stem (caulome) is an axis capable of bearing leaves and (directly or indirectly) the proper reproductive organs. The leaf (phyllose) is an appendicular member only borne by a stem, but differing from it more or less obviously in form and development, though co-ordinate with it in complexity of structure. The root is an axis which never bears either leaves or the proper reproductive organs (whether sexual or asexual) of the plant. The hair (trichome) is a superficial appendage of simple structure, which may be borne by any of the other members. The emergence is also an appendicular member of more complex structure than the hair (e.g. the prickles of the rose). Further, it has been found convenient to designate the leaf-bearing stem as a whole by the term shoot, so that the body may, as Sachs suggested, be primarily analysed into shoot and root.

At the present time some objection is being taken to this purely morphological conception of the body and its parts as being too abstract. It is urged that the various parts are, as a matter of fact, organs; and that it is therefore inadmissible to ignore their functions, as is done in the foregoing definitions. To this it may be replied that pure morphology and organography are not alternatives, but are two complementary and equally necessary modes of considering the composition of the plant-body. Moreover, the abstract terms "stem," "leaf," "root," etc., are absolutely indispensable; and are continually used in this sense by the most ardent organographers. It has not yet been suggested that they should be replaced by organographical terms; were this accomplished, descriptive botany would become impossible.

It is also urged against these definitions that they are not of universal applicability; that there are exceptional structures which cannot be brought within the limits of any one of them. But admitting the validity of this criticism, and even going so far as to question the possibility of ever devising absolutely inclusive and, at the same time, exclusive definitions, no sufficient reason is adduced for giving up all attempt at morphological and physiological definitions.

Homology.—All members belonging to the same morphological category are said to be homologous, however diverse their functions. Thus, in a phanerogam, the sepal, petals, stamens and foliage-leaves all come under the category leaf; though some are parts of the perianth, others are spore-bearing organs (sporophylls), and others carry nutritive processes. The homology of members was based, in the first instance, upon similarity of development and upon similar relations to the other parts of the body, that is, upon ontogeny. But since the general adoption of the theory of evolution, similarity of descent, that of phylogeny, has come to form an essential part of this conception; and, in other words, in order that their homology may be established the parts compared must be proved to be homologous.

The introduction of the phylogenetic factor has very much increased the difficulty of determining homologies; for the data necessary for tracing phylogeny can only be obtained by the study of a series of allied, presumably ancestral, forms. One of the chief difficulties met with in this line of research, which is one of the more striking developments of modern morphology, is that of distinguishing between organs which are "reduced," and those which are really "primitive." The object of the phylogenetic study of any organ is to trace it back to its primitive form. But, as will be pointed out later, organs are often found to have undergone "degeneration" or "reduction," and such reduced or degenerate structures may easily be mistaken for primitive structures, and so the investigator may be misled.

The effect of the phylogenetic factor in homology may be illustrated in the following cases. The leaves of the true mosses and those of the club-mosses (Lycopodium, Selaginella) being somewhat alike in general appearance and in ontogeny, might be, and indeed have been, regarded as homologous on that ground. However, they belong respectively to two different forms in the life-history of the plants; the leaves of the mosses are borne by the gametophyte, those of the club-mosses by the sporophyte. In accordance with the prevalent antithetic view of the alternation of generations in these plants (see PLANTS, REPRODUCTION OF), the forms distinguished as sporophyte and gametophyte are not homogenic; consequently their leaves are not homologous, but are only functionally similar (homoplastic; see infra).

Another effect is that different degrees of homology have to be recognized, just as there are different degrees of relationship or affinity between individual plants. When two organs can be traced along the same line of descent to one primitive form, that is when they are found to be monophyletic, their homology is complete; when, however, they are traceable to two primitive forms, though these forms belong to the same morphological series, they are polyphyletic and therefore only incompletely homologous. For instance, all the leaves of the Bryophyta are generally homologous inasmuch as they are all developments of the gametophyte. But there is reason to believe that they have differentiated quite independently in various groups, such as the Marchantiaceae, the Jungermanniaceae, and the mosses proper; consequently their phylogeny is not the same, they are polyphyletic, and therefore they are not completely homologous, but are parallel developments.

Analogy.—Considering the parts of the body in relation to their functions, that is as organs, they are found to present peculiarities of form and structure which are correlated with the functions that they have to discharge; in other words, the organ shows adaptation to its functions. All organs performing the same function and showing similar adaptations are said to be analogous or homoplastic, whatever their morphological nature may be; hence organs are sometimes both homologous and analogous, sometimes only analogous. The tendrils of a vetch and of a cucumber are analogous, and also homologous because they both belong to the category leaf; but they are only analogous to the tendrils of the vine and of the passion-flower, which belong to the category stem.

Metamorphosis.—It has already been pointed out that each kind of member of the body may present a variety of forms. For example, a stem may be a tree-trunk, or a twining stem, or a tendril, or a thorn, or a creeping rhizome, or a tuber; a leaf may be a green foliage-leaf, or a scale protecting a bud, or a tendril, or a pitcher, or a floral leaf, either sepal, petal, stamen or carpel (sporophyll); a root may be a fibrous root, or a swollen tap-root like that of the beet or the turnip. All these various forms are organs discharging some special function, and are examples of what Wolff called "modification," and Goethe "metamorphosis." It may be inquired what meaning is to be attached to these expressions, and what are the conditions and the nature of the changes assumed by them. The leaf of the higher plants will be taken as the illustration, and it is seen that it is most "plastic" of the members, the one, that is, which presents the greatest variety of adaptations, and because it has been most thoroughly studied.

In this, as in all morphological inquiries, two lines of investigation have to be followed, the phylogenetic and the ontogenetic. Beginning with its phylogeny, it appears, so far as present knowledge goes, that the differentiation of the shoot of the sporophyte into stem and leaf first occurred in the Pteridophyta; and, in accordance with the views of Bower (Origin of a Land-Flora), the primitive leaf was a reproductive leaf, a sporophyll, from which the foliage-leaf was derived by progressive sterilization. From the nature of the case, this view is not, and could not be, based upon actuality, and this view is still in many cases not accepted; however, it seems to correspond more closely than any other to the facts of comparative morphology. It was formerly assumed, and the view is still held, that the foliage-leaf was the primitive form from which all others were derived, mainly on
the ground that, in ontogeny, the foliage-leaf generally precedes the sporophyll. The phylogeny of the various floral leaves, for instance, was generally traced as follows: foliage-leaf, bract, sepal, petal, stamen and carpel (sporophylls)—in accordance with what Goethe termed “ascending metamorphosis.” Recent researches, however, especially those of Celakovsky, tend to prove that the perianth-leaves have been derived from the stamens (i.e. from sporophylls); that is, they are the result of “descending metamorphosis.” Moreover there is the fact that the flowers of nearly all the primitive phanerogams, such as the Gymnosperms, consist solely of sporophylls, having no perianth. There is thus a considerable body of evidence to support Bower’s view of the primitive nature of the sporophyll.

Accepting this view of the phylogeny of the leaf, the perianth-leaves (sepals and petals) and the foliage-leaves may be regarded as modified or metamorphosed “sporophylls; that is, as leaves which are adapted to functions other than the bearing of spores. The sepals are generally organs for the protection of the flower-bud; the petals, for attracting insects by their conspicuous form and colour; the foliage-leaves, for the assimilation of carbon dioxide and other associated functions. But this phylogenetic differentiation of the organs was not what Wolff and Goethe had in mind; what they contemplated was an ontogenetic change, and there is abundant evidence that such changes actually occur. Taking first the conversion of members of one morphological category into those of another, this has been actually observed, though rarely. Goebel (Organography) gives several instances of the conversion of the root into a shoot in ferns, and a few in phanerogams (Listera ovata, Neottia nidus-avis, Anthurium longifolium). Much more common is the conversion of one form of a member into another form. The most varied changes of this kind have been described, and are generally familiar as “monstrosities”; the study of them constitutes, under the name of teratology, a distinct department of biology. A simple case is that of “double” flowers, in which the number of the petals is increased by the “metamorphosis” of stamens; or again the conversion of floral leaves into green leaves, a change known as “chloranthy”. These changes may be brought about by external causes, such as the attacks of insects or of fungi, alterations in external conditions, &c., or by some unexplained internal disturbance of the morphological equilibrium. They can also be effected experimentally. Goebel has shown that if the developing foliage-leaves of the fern Onocea struthioperis be removed as they are formed, the subsequently developed sporophylls assume more or less completely the habit of foliage-leaves, and may be sterile. Similarly bud-scales can be caused to develop into foliage-leaves, if the buds to which they belong are caused to grow out in the year of their formation by the removal of the existing foliage-leaves.

Useful and suggestive as they often are, teratological facts played, at one time, too large a part in the framing of morphological theories; for it was thought that the “monstrous” form gave a clue to the essential nature of the organ assuming it. There is, however, no sufficient reason for regarding the monstrous form as necessarily primitive or ancestral, nor even as a stage in the ontogeny of the organ. For when the older morphologists spoke of a stamen as a “metamorphosed” leaf, it was implied that it originated as a foliage-leaf and subsequently became a stamen. As a matter of fact, a stamen is a stamen and nothing else, from the very beginning. The development of the organ is already determined at its first appearance upon the growing-point; though, as already explained, the normal course of its ontogeny may be interfered with by some abnormal external or internal condition. The word “metamorphosis” cannot, in fact, be used any longer in its original sense, for the change which it implied does not normally occur in ontogeny, and in phylogeny the idea is more accurately expressed by the term “differentiation.” However, it may still be useful in describing “monstrosities,” and perhaps also those cases in which an organ serves first one purpose and then another, as when a leafy shoot eventually becomes a thorn, or the base of a foliage-leaf becomes a bud-scale.

Differentiation.—Any account of the general morphology of living organisms is incomplete if it does not include some attempt at an explanation of its causation; though such an attempt cannot be carried far at the present time. A survey of the vegetable kingdom indicates that evolution has proceeded, on the whole, from the simple to the complex; at the same time, as has been already mentioned, evidence of reduction or degeneration is common. Thus in the series Bryophyta, Pteridophyta, Phanerogamia, whilst the sporophyte presents progressive development, the gametophyte presents continuous reduction.

Evolution means the gradual development of “highly organized” from “lowly organized” forms; that is, of forms in which the “physiological division of labour” is more complete, from those in which it is less complete; of forms possessing a variety of organs, from forms possessing but few. Differentiation means the development and the specialization as organs of various parts of the body. It presents itself in two aspects: there is morphological differentiation, which can be traced in the distinctness of the members of the body, root, stem, leaf, &c.; there is physiological differentiation, which can be traced in the adaptation of these members to various functions. But, in actual operation, these two processes are simultaneous; every member is developed as an organ for the performance of some special function.

Factors in Evolution.—Evolution in the race involves progressive differentiation in the individual; hence the causes of evolution and of differentiation must be the same. The evolution of higher from lower plants, it is generally assumed, has proceeded by variation. With regard to the causation of variation Darwin says (Origin of Species, ch. v.): “In all cases there are two factors, the nature of the organism, which is much the most important of the two, and the nature of the conditions. The direct action of changed conditions leads to definite or indefinite results. In the latter case the organization seems to become plastic, and we have much fluctuating variability. In the former case the nature of the organism is such that it yields readily, when subjected to certain conditions, and all or nearly all the individuals become modified in the same way.”

In spite of the statement that the “nature of the organism” is the most important factor in variation, the tendency amongst evolutionists has been to take much more account of the influence of external conditions. Exceptions to this attitude are Lamarck, who speaks with regard to animals (but not to plants) of “la composition croissante de l’organisation” (Philosophie zoologique, t. i.), and Nägeli, who attributes variation to causes inherent in the “idioplasm,” and has elaborately worked out the view in his Abstammungsslehre.

The position assumed in this article is in agreement with the views of Lamarck and of Nägeli. All but the lowest plants visibly tend towards or actually achieve in various degrees the differentiation of the body, whether sporophyte or gametophyte, into stem, leaf, root, &c., that is, the differentiation of parts not previously present. It is inconceivable that external conditions can impart to an organism the capacity to develop something that it does not already possess: can impart to it, that is, the capacity for variation in the direction of higher complexity. The alternative, which is here accepted, is that differentiation is essentially the expression of a developmental tendency inherent in the protoplasm of plants. Just as every crystallizable chemical substance assumes a definite and constant crystalline form which cannot be accounted for otherwise than by regarding it as one of the properties of the substance, so every living organism assumes a characteristic form which is the outcome of the properties of its protoplasm. But the outcome of the same formative property of a chemical substance is stable and fixed, the organized form of a living organism is unstable and subject to change.

Influence of External Conditions.—This position does not, however, exclude the influence of external conditions; that influence is undeniable. Darwin’s expression “the nature of the organism” has been interpreted in the preceding paragraph to mean an inherent tendency towards higher organization; that interpretation may now be completed by adding that the
organism is susceptible to, and can respond to, the action of external conditions. There is every reason to believe that plants are as "irritable" to varying external conditions as they are to light or to gravity. A change in its external conditions may act as a "stimulus," evoking in the organism a response of the nature of a change in its form. As Darwin has pointed out, this response may be direct or indirect. In illustration of the indirect response, the evolution of the Bryophyta and of more highly organized plants may be briefly considered. It is generally admitted that life originated in water, and that the earliest plants were Algae. The study of existing Algae, that is of plants that have continued to live in water, shows that under these conditions no high degree of organization has been reached, though some of them have attained gigantic dimensions. The primitive water-plants were succeeded by land-plants, a land-flora being gradually established. With the transition from water to land came the progressive development of the sporophyte which is the characteristic feature of the morphology of the Bryophyta and of all plants above them in the scale of life (see Bower, Origin of a Land-Flora). This evolution of the sporophyte is no doubt to be correlated with the great change in the external conditions of life. There is no conclusive ground for regarding the action of this change as having been direct, it is more reasonable to regard it as indirect, having acted as a general stimulus to which the ever-increasing complexity of the sporophyte was the response.

Adaptation.—The morphological and physiological differentiation of the plant-body has, so far, been attributed to (1) "the nature of the organism," that is to its inherent tendency towards higher organization, and (2) to the "indefinite results" of the external conditions acting as a stimulus which excites the organism to variation, but does not direct the course of variation. The "indefinite results" of the action of external conditions have still to be considered.

It is a familiar observation that climatic and edaphic (nature of soil) conditions exert an influence upon the form and structure of plants (see Plants: Ecology of). For instance, some xerophytes are dry and hard in structure, whilst others are succulent and fleshy. This so-called direct effect of external conditions upon the form and structure of the body differs from the indirect effect in that the resulting variations bear a relation, of the nature of adaptation, to those conditions; the effect of the conditions is thus capable of continuing to cause variation in a particular direction. Thus all existing organisms (excepting the Algae) are considered to have been derived from land-plants which have adapted themselves to a watery habitat. The effect can also be demonstrated experimentally: thus it has been observed that a xerophyte grown in moist air will lose its characteristic adaptive features, and may even assume those of a hygrophyte.

Climatic and edaphic conditions are not, however, the only ones to affect the structure and composition of the body or its parts; other conditions are of importance, particularly the relations of the plant to animals and to other plants. For instance, the "characteristic organs" of carnivorous plants (Drosera, Nepenthes, &c.) did not, presumably, arise in connection with the plant's habit as such, but began as organs of quite another kind which became adapted to their present function in consequence of animals having been accidentally caught. It is also probable that the various forms of the angiospermous flower, with its many specialized mechanisms for pollination, may be the result of insect-visits, the flowers becoming adapted to certain kinds of insects, and the insects having undergone corresponding modification. Parasites, again, were derived from normal autotrophic plants, which, as the parasitic habit became more pronounced, acquired the corresponding characteristics of form and structure; there is, in fact, the group of true-parasites, plants which still retain autotrophic characters though they are root-parasites.

Though adaptation to the environment seems sometimes to be considered, especially by neo-Lamarckians, as equivalent to, or at least as involving, the evolution of higher forms from lower, there does not appear to be any evidence that this is the case. The effect of external conditions is confined to the modification in various directions of members or organs already existing, and one very common direction is that of reduction or entire disappearance of parts: for instance, the foliage-leaves of certain xerophytes (e.g. Cactaceae, Euphorbiaceae), of parasites, and of saprophytes. Moreover, had the evolution of plants proceeded along the line of adaptation, the vegetable kingdom could not be subdivided; as it is, it is divided into the morphological groups Thallophyta, Bryophyta, Pteridophyta, Phanerogamia, but only into physiological groups, Xerophyta, Hygrophyta, Tropophyta, &c.

In endeavouring to trace the causation of adaptation, it is obvious that it must be due quite as much to properties inherent in the plant as to the action of external conditions; the plant must possess adaptive capacity. In other words, the plant must be irritable to the stimulus exerted from without, and be capable of responding to it by changes of form and structure. Thus there is no essential difference between the "direct" and the "indirect" action of external conditions, the difference is one of degree only. In the one case the stimulus induces indefinite variation, in the other definite; but no hard-and-fast line can be drawn between them.

Adaptive characters are often hereditary, for instance, the seed of a parasite will produce a parasite, and the same is true of a carnivorous plant. On the other hand, adaptations, especially those evoked by climatic or edaphic conditions, may only be shown by the seedling if grown under the appropriate external conditions; here what is hereditary is not the actual adaptation, but the capacity for responding in a particular way to a certain set of external conditions.

Summary.—The general theory of differentiation propounded in this article is an attempt at an analysis of the factors termed by Darwin "the nature of the organism" and "the nature of the conditions." It is assumed, as an inevitable conclusion from the facts of evolution, that plant-protoplasm possesses (1) an inherent tendency towards higher organization, and (2) that it is irritable to external conditions, or to changes in them, and can respond to them by changes of form which may be either indefinite or definite (adaptive). Thus it is that the variations are produced upon which natural selection has to work.

Material Cause of Differentiation.—It may be inquired, in conclusion, if there are any facts which throw light upon the internal mechanism of differentiation, whether spontaneous or induced. It is possible to refer it to any material cause. It may be replied that there are such facts, and though they are but few as yet, they suffice to suggest a hypothesis that may eventually prove to be a law. Sachs was the first to formulate the theory that morphological differences are the expression of differences in material composition. He considered, for instance, that stems, leaves, roots and flowers differ as they do because the plastic substances entering into their structure are diverse. This view he subsequently modified to this—that a relatively small proportion of diverse substance in each of these parts would suffice to account for their morphological differences. This modification is important, because it transfers the formative influence to the substances involved, as we see, for instance, that there are constant relations governing that the diverse constituents are produced (whether spontaneous or as the result of stimulation) as secretions by the protoplasm. It is an obvious inference that if a small quantity of a substance can affect the development of an entire organ it probably acts after the manner of an enzyme. Bayerink has, in fact, gone so far as to speak of "formative enzymes."
structure. If this be so, it may justifiably be inferred that both normal and abnormal morphological features may be due to the presence of enzymatic substances secreted by the protoplasm that determine the course of development. At any rate this hypothesis suggests an explanation of many hitherto inexplicable facts. For instance, it has been pointed out in the article on the reproduction of plants that the effect of the fertilization of the female cell in the ovule of phanerogam is not confined to the female cell, but extends more or less widely outside it, inducing growth and tissue-change. The ovule develops into the seed; and the gynaeceum and even more remote parts of the flower, develop into the fruit. The facts are familiar, but there is no means of explaining them. In the light of Sachs's theory the interpretation is this, that the act of fertilization causes the formation in the female cell of substances which are transmitted to adjacent structures and stimulate them to further development.

LITERATURE.—As the scope of this article limits it to the general principles of the morphology of plants, comparatively few facts have been adduced. Full morphological and organographical details are given in the articles on the various groups of plants, such as the Algae, Bryophyta, Pteridophyta, Angiosperms, Gymnosperms, &c. The reader will also be referred to Schimper, Plant-Geography (Clarendon Press, Oxford); Goebel, Organography (Clarendon Press, Oxford); Bower, The Origin of a Land-Flora (Macmillan); Beyerineck, "Ueber Céclidin." (Bot. Zeitung, 1888).

DISTRIBUTION OF PLANTS

Common experience shows that temperature is the most important condition which controls the distribution of plants. Those of warmer countries cannot be cultivated in British gardens without protection from the rigours of winter; still less are they able to hold their own underground in an unfavourable climate. Temperature, then, is the fundamental limit which nature opposes to the indefinite extension of any one species. Buffon remarked "that the same temperature might have been expected, all other circumstances being equal, to produce the same beings in different parts of the globe, both in the animal and vegetable kingdoms." Yet lawns in the United States are destitute of the common English daisy, the wild hyacinth of the woods of the United Kingdom is absent from Germany, and the foxglove from Switzerland. We owe to Buffon the recognition of the limitation of groups of species to regions separated from each other by land and ocean, in other words, as he put it, "man when he surmounts these, they often dominate with unexpected vigour the native vegetation amongst which they are colonists. The cardoon and milk thistle, both European plants, cover tracts of country in South America with impenetrable thickets in which both man and beast may be hopelessly lost. The watercress blocks the rivers of New Zealand into which it has been introduced from Europe. The problem, then, which plant-distribution presents is twofold: it has first to map out the earth's surface into "regions" or "areas of vegetation," and secondly to trace the causes which have brought them about and led to their restriction and to their mutual relations.

The earliest attempts to deal with the first branch of the inquiry were called physiognomical. They endeavoured to define "aspects of vegetation" in which the "forms" exhibited an obvious adaptation to their climatic surroundings. This has been done with success and in great detail by Grisebach, whose "Vegetation der Erde" from this point of view is still unsurpassed. With it may be studied with advantage the unique collection at Kew of pictures of plant-life in its broadest aspects, brought together by the industry and munificence of Miss Marianne North. Grisebach declined to see anything in such "forms" but the production by nature of that which responds to external conditions and can only exist as long as they remain unchanged. We may agree with him that such a point of view is obsolete without rejecting as valueless the admirable accumulation of data of which it admittedly fails to give any rational explanation. A single example will be sufficient to illustrate this. The genus Senecio, with some 1000 species, is practically cosmopolitan. In external habit these exhibit adaptations to every kind of climatic or physical condition: they may be mere weeds like groundsel or ragwort, or climbers masquerading like ivy, or succulent and almost leafless, or they may be shrubs and even trees. Yet throughout they agree in the essential structure of their floral organs. The cause of such agreement is, according to Grisebach, shrouded in the deepest obscurity, but it finds its obvious and complete explanation in the descent from a common ancestor which he would unhesitatingly reject.

From this point of view it is not sufficient, in attempting to map out the earth's surface into "regions of vegetation," to have regard alone to adaptations to physical conditions. We are compelled to take into account the actual affinity of the plants inhabiting them. Anything short of this is merely descriptive and empirical, and affords no rational basis for inquiry into the mode in which the distribution of plant-life has been brought about. Our regions will not be "natural" unless they mark out real discontinuities both of origin and affinity, and these we can only seek to explain by reference to past changes in the earth's history. We arrive thus at the essential aim of geographical botany," which, as stated by Schimper, is "an inquiry into the causes of differences existing among the various floras." To quote further: "Existing floras exhibit only one moment in the history of the earth's vegetation. A transformation which is sometimes rapid, sometimes slow, but always continuous, is wrought by the reciprocal action of the innate variability of plants and of the variability of the external factors. This change is due partly to the migrations of plants, but chiefly to a transformation of the plants covering the earth. This transformation is due to new characters arising through variation. "If the new characters be useful, they are selected and perfected in the descendants, and constitute the so-called 'adaptations' in which the external factors acting on the plants are reflected." The study of the nature of these adaptations, which are often extremely subtle and by no means merely superficial, is termed Ecology (see above).

The remark may conveniently find its place here that plants which have reached a high degree of adaptive specialization have come to the end of their tether: a too complicated adjustment has deprived them of the elasticity which would enable them to adapt themselves to any further change in their surroundings, and they would pass away with conditions with which they cannot still be in perfect agreement. In this way less useful forms, thus found their grave in geologic change. That brought by man in destroying forests and cultivating the land will be no less effective, and already specimens in our herbaria alone represent species no longer to be found in a living state. Extinction may come about indirectly and even more surely. This is easy to happen with plants dependent on insects for their fertilization. Kronfeld has shown that aconites are dependent for this on the visits of a Bombus and cannot exist outside the area where it occurs.

The actual and past distribution of plants must obviously be controlled by the facts of physical geography. It is concerned with the land-surface, and this is more symmetrically disposed than would at first sight appear from a glance at a map of the world. Lyell points out that the eye of an observer placed above a point between Pembroke and Wexford, lat. 52° N. and long. 6° W., would behold at one view the greatest possible quantity of land, while the opposite hemisphere would contain the greatest quantity of water. The continental area is on one side of the sphere and the oceanic on the other. Love, has shown (Nature, Aug. 1, 1907, p. 328) that this is the result of physical causes and that the existence of the Pacific Ocean "shows that the centre of gravity of the earth does not coincide with the centre of figure." One half of the earth has therefore a greater density than the other. But "under the influence of the rotation the parts of greater density tend to recede further from the axis than the parts of less density . . . the effect must be to produce a sort of furrowed surface." The furrows are the great ocean basins, and these would still persist even if the land surface were enlarged to the 14,00 fathoms contour. These considerations
PLANTS

preclude the possibility of solving difficulties in geographical distribution by the construction of hypothetical land-surfaces, an expedient which Darwin always stoutly opposed (Life and Letters, ii. 74-78). The furrowed surface of the earth gives the land-area a star-shaped figure, which may from time to time have varied in outline, but in the main has been permanent. It is exectic as regards the pole and sends tapering extensions towards the south. Sir George Darwin finds a possible explanation of these in the screwing motion which the earth would suffer in its plastic state. The polar regions travelled a little from west to east relatively to the equatorial, which lagged behind.

The great primary divisions of the earth's flora present themselves at a glance. The tropics of Cancer and Capricorn cut off with surprising precision (the latter somewhat less so) the tropical from the north and south temperate zones. The north temperate region is more sharply separated from the other two than the south temperate region from the tropical.

I. NORTH TEMPERATE REGION (Holartic).—This is the largest of all, circumglobal, and but for the break at Bering Straits, would be, as it has been in the past, continuous in both the old and new worlds. It is organized as a whole of needle-leaved Coniferæ, the catkin-bearing (Amentacese) and other trees, deciduous in winter, and its profusion of herbaceous species.

II. SOUTH TEMPERATE REGION. —This occupies widely separated areas in South America, Australia, New Zealand, and South Africa. These are connected by the presence of peculiar types, Proteaceæ, Restiaceæ, Rutaceæ, &c., mostly shrubby in habit and on the whole, somewhat intolerant of a moist climate. Individual species are extensively distributed, but not in a circumglobal sense, and the vegetation of the globe had already in its main features been constituted at this period much as it exists at the present moment. There are beeches (scarcely distinguishable from existing species), birches, palm-leaved trees, and the curious Castanospermum, which, thinned out by losses, practically exists to this day in the same conditions as in the great forest pioneer period. Here one essentially similar but adapted to slightly cooler conditions existed as far north as the latitude of Greenland.

The Miocene epoch, largely a period of degeneration, is one in which the Eocene period something like existing tropical conditions must have obtained in the northern hemisphere. The remains of palms (Sabal and Nipa) as well as of other large-leaved Monocotyledons are preserved. In South America, the genera Zelkova and Aucuparia (introduced to Europe, which have yielded the very popular trees and ornamental trees of Conifères (including the living spruce), poplars and willows, such as would be found now 25° to the south. The flora of Disco Island in lat. 70° contained Sequoia, planes, maples and magnolias, and closely agrees with the Miocene flora of central Europe. Of this copious remains have been found in Switzerland and have been investigated with great ability by O. Heer. They point to cooler conditions in the northern hemisphere; palms and tropical types diminish, deciduous forms increase, and a great variety of Conifères still remain; figs are abundant; laurels are represented by Sassafras and camphor; herbaceous plants (Ranunculaceæ, Crucifèreæ, Umbellifèreæ) are present, though, as might be expected, only fragmentary preserved.

We may draw with some certainty the conclusion that a general movement southward of vegetation had been brought about. While Europe had probably lost its a subtropical flora which has been compared with that existing at present in Australia. Upper Cretaceous formations in America have yielded a copious flora of a warm-temperate climate from which it is evident that at least the generic types of numerous not closely related existing dicotyledonous trees had already come into existence. It may be admitted that the identification of fragmentary leaf-leaves is at most precarious. Even, however, with this reservation, it is difficult to resist the mass of evidence that alludes to a vast differentiation. If the vegetation of the globe had already in its main features been constituted at this period much as it exists at the present moment. There are beeches (scarcely distinguishable from existing species), birches, palm-leaved trees, and the curious Castanospermum, which, thinned out by losses, practically exists to this day in the same conditions as in the great forest pioneer period. We may draw with some certainty the conclusion that a general movement southward of vegetation had been brought about. While Europe had probably lost its a subtropical flora which has been compared with that existing at present in Australia. Upper Cretaceous formations in America have yielded a copious flora of a warm-temperate climate from which it is evident that at least the generic types of numerous not closely related existing dicotyledonous trees had already come into existence. It may be admitted that the identification of fragmentary leaf-leaves is at most precarious. Even, however, with this reservation, it is difficult to resist the mass of evidence that alludes to a vast differentiation. If the vegetation of the globe had already in its main features been constituted at this period much as it exists at the present moment. There are beeches (scarcely distinguishable from existing species), birches, palm-leaved trees, and the curious Castanospermum, which, thinned out by losses, practically exists to this day in the same conditions as in the great forest pioneer period. Here one essentially similar but adapted to slightly cooler conditions existed as far north as the latitude of Greenland.
PLANTS

DISTRIBUTION

has been brought about rather by extermination than specialization, and their distinctive facies by the development and multiplication of new and different forms of life.

The distribution of mountain barriers in the Old and New Worlds is in striking contrast. In the former they run from east to west; in the latter from north to south. In the Old World the boreal zone is usually more or less zoned in a series of horizontal belts, each differing in flora and fauna. In the New World it is more as if a wall had been thrown up, with the growth of this wall being due to the plants and animals of the higher altitudes. So the Miocene vegetation theory when the climate became more severe. Thus in the Mediterranean region the large groups of palms, figs, myrtles and laurels were replaced by single surviving species. The great tropical family of the Gomphocarpus is scarce in the Old World, but so abundant in the New.

In North America there is no such barrier; the Miocene flora has been able to escape by migration the fluctuations of climate and to return when they ameliorated. It has preserved its characteristic types, and therefore is of great use to the student of climate. Vegetation as a whole is a well-marked example of the degree, "in every latitude of the globe, and is the only one that is so" (Trans. Linn. Soc. x. 253). In the mountains of Peru we find such characteristic northern genera as Gentiana, Peuce, Gentianella, Dryas, and several others, and species, such as Peuce, Peuce, and Peuce, which are absent from the New World.

The aequor vapour in the atmosphere is transparent to luminous but opaque to heat-rays. The latter are retained to warm the earth, and it remains in the atmosphere that besides a horizontal distribution of plants, there is also an altitudinal; a fact of cardinal importance, the first observation of which is due to Trees, as early as 1820.

Speaking generally, all plants tend to exhaust particular constituents of the soil on which they grow. Nature therefore has provided various contrivances by which their seeds are disseminated because they are dispersed to land and sea. On these only provide for migration within sufficient but narrow limits; such plants would be content to remain local. But other physical agencies come into play which may be briefly noticed. The first of these is the wind. It is well known that small seeds can be swept up like dust and transported to considerable distances. This is certainly the case with fern-spores. The vegetation of Krakatoa was completely exterminated in 1883 by a thick coat of red-hot pumice and ashes; to the west of Britains, for example, these only provide for migration within sufficient but narrow limits; such plants would be content to remain local. But other physical agencies come into play which may be briefly noticed. The first of these is the wind. It is well known that small seeds can be swept up like dust and transported to considerable distances. This is certainly the case with fern-spores. The vegetation of Krakatoa was completely exterminated in 1883 by a thick coat of red-hot pumice and ashes; to the west of Britains, for example, such as the crowberry (Empetrum nigrum), Trientalis europaea, Rubus saxatilis and the globe-flower (Trollius europaeus).

If we limiting the area of one that is so "(Trans. Linn. Soc. x. 253). In the mountains of Peru we find such characteristic northern genera as Gentiana, Peuce, Gentianella, Dryas, and several others, and species, such as Peuce, Peuce, and Peuce, which are absent from the New World.

It remains to be seen how far the principles of the species theory may be adjusted to the world of plants. It is not easy to say; but it seems to me that no one has yet attempted to do so. 1. The Arctic-Alpine sub-region consists of races of plants belonging originally to the general flora, and recruited by subsequent accessions. The flora had already been established by the time that the Scots fir, which is now extinct, was abundant in Denmark in the Roman period. It was succeeded by the sessile-fruited oak, which in turn succeeded by its pedunculate form of the same species. Quercus Robur has left no trace of the former, but is still present in Europe and it is mostly allied to east Asian species. The oak in turn has been almost superseded in Denmark by the beech, which, however, has found a niche for itself above the zone above which the Aletsch glacier at a height of 10,700 ft. Ball found the temperature one inch below the surface to be 83°, and he collected "over forty species in flower." Taking the whole arctic flora at 702 species, Heddle, the naturalist who carried out the work, gives 37 species. The arctic flora contains no genus that is peculiar to it, and only some fifty species that are so. Christ has objected to terming the arctic flora Scandinavian, but the name implies nothing more than that Scandinavia has been its chief place of preservation.

A detailed examination of mountain floras shows that a large local element is present in each besides the arctic. The one is in fact the result of the severe conditions of the previous cold climate which has affected the whole Ural-Mongolian area. The Ural-Mongolian flora contains no genus that is peculiar to it, and only some fifty species that are so. Christ has objected to terming the arctic flora Scandinavian, but the name implies nothing more than that Scandinavia has been its chief place of preservation.

The repetition of the same species in the arctic regions and in the high mountains of the North Temperate region is generally attributed to the exchange which took place during the glacial period. This was first suggested by Edward Forbes in 1846, though the idea had earlier suggested by Dr. J. D. Hooker (1846). It was developed by Darwin (1849) and others, and is now recognized as a natural law. The idea has been adopted by almost every naturalist who has studied the subject, and it is probably the most important fact in the study of the distribution of plants. It is based on the assumption that the climate of the present day is different from that of the past, and that therefore the plant communities of the present day are different from those of the past. This assumption is probably correct, but it is difficult to prove.

The idea of the exchange of plant communities has been applied to the study of the distribution of plants in the arctic regions. The idea is that the arctic flora is a mixture of the floras of the boreal and alpine regions. The idea is illustrated by the fact that the arctic flora contains many species that are also found in the boreal and alpine floras. The idea is also illustrated by the fact that the arctic flora contains many species that are also found in the floras of other regions. The idea is illustrated by the fact that the arctic flora contains many species that are also found in the floras of other regions.

species are known out of a probable total of not less than 12,000, and of these more than half are endemic. The number of species to which one is said to have given rise to a large and very distinctive aggregation of genera and of endemic species is characteristic of the circumferential portions of the earth’s land surface: the expansion of the Atlantic Ocean and the Arctic area at the northward advance of the other is arrested. The sub-region is probably the most peculiarly and clearly defined of all the Mediterranean-oriental sub-regions and is still more remote. China has 40% of the plants of Manchuria are common to Europe and Asia, but the proportion falls sharply to 16% in the case of Madeira where the Mediterranean-Oriental sub-region is still more remote. China has 40% of the plants of the forest known to be in China. Japan has 66 species of Quercus, Aesculus, of Acer, 33 Magnoliaceae (including two species of Colletia litoris), 12 Annonaceae, 71 Ternstroemiaceae (including the teak, Tectona grandis), Myristicaceae, western representative in Madeira. Trachycarpus and Rhapis are distinctive palm species, and Cynadaceae are represented by Cynade.

Asiatic America sub-region has as its northern boundary the parallel of lat. 36° as far as New Mexico and the main coast to the Pacific coast at lat. 40°. The eastern and western halves are contrasted in climate—the former being moist and the latter dry—and have been distinguished by some zoologists as distinct sub-regions. They are in fact distinguished by the endemic sub-regions that of eastern North America. Not, with perhaps the interesting exception of Castanopsis chrysophylla, the solitary representative in the New World of an east Asiatic genus, which ranges from Oregon to Alaska and Canada, is a genus of distinct affinity with the sub-region. Its closest connexion is with the South American Andin.

II. THE TROPICAL REGION.—The permanence of continents and great oceans was first insisted upon by J. D. Dana, but, as already stated, at least one supporting connexion precludes the explanation of all common features in the dismembered portions of the tropical area of vegetation by lateral communication, and throws back their origin to the remoter geological antiquity. In the Great American Flora, the very genera which are reckoned to be the main component of the flora of the American continent, it is probable that they are derived from the same source as the genera of the New World. The plants which are represented by groups of species scattered through the tropics of both worlds, one reaching Polynesia.

South American sub-region.—Western Arabia must be added to the African continent, which, with this exception and possibly a former European connexion in the far west, has had apparently from a very early period an alien insular character. Botham remarks (Journ. Linn. Soc., xliii., 1902): “Here, more perhaps than anywhere, the sub-region is entirely absent. But including the Mascarene Islands and Seychelles the Borassae are exclusively African. Aroidae are poorly represented compared with either South America or Malay. A peculiar feature in which the tropical African stands alone is that at least one-fifth and probably more of the species are endemic to both sides of the continent and presumably stretch right across it. The central highlands of the continent to the north-east is most marked on the eastern side: the Himalayan Gloriosa will suffice as an example, and of more tropical types Phoenix and Calathea. The flora of Madagascar is the most localised at present of any island, including an endemic family Chamaesaceae, essentially tropical African, and the upland flora south temperate. 2. Indo-Malayan sub-region includes the Indian and Malay peninsula, Ceylon, the Philippines, Javan, Sumatra, Celebes, and the island of Madagascar, though including an endemic family Chamaesaceae, essentially tropical African, and the upland flora south temperate.
now unrepresented anywhere but in South Africa. This flora extends from Ireland to the Canaries and reappears on the highlands of Angola. On the eastern side the southern flora finds representatives in Abyssinia and in the Proteaceae Cape, Kaelderson capensis occurring on Kilimanjaro. This is the most northern representative of the Rutaceous Diosmaceae, which are replaced in Australia by the Boronineae. The Proteaceae generally dominates the flora of the South African desert, and the succulent genus Pelargonium has a few Mediterranean representatives, and one even occurs in Asia Minor. In all these cases it is a question whether we are tracing an ascending or descending stream. South Africa is isolated much as Australia is to Europe, and the faunal or floras of the Southern Hemisphere show a similar tendency towards a succulent habit. The nearly related Ficoideae replace the new-world Cactaceae, but the habit of the latter is simulated by Fleshy Euphorbias and Acaena, just as that of the desert in South Africa has only two palms (Phoenix and Hyphaene). In the Gnetaceous Welwitschia it possesses a vegetable type whose extraordinary peculiarity makes it seem amongst contemporaneous vegetation much as some strange extinct animal form would if suddenly endowed with life. Conifers are scantily represented by Calitris and Podocarpus, which is common to all three sub-regions; and Cycads by the endemic Encephalartos and Stroemia. 2. The Australian sub-region consists of Australia, Tasmania, New Caledonia and New Zealand, and, though partly lying within the tropic is most naturally treated as a whole. They are linked together by their vegetation from its limits, the sub-tropical, to take the place of the nearly allied heaths in South Africa. The most dominant order in Australia is Leguminoseae, including the acacias with leafast, plume-bearing flowers, and, as usual, the Melaleuca, which is represented in New Caledonia and New Zealand; a few species of the former extend to New Guinea and one of the latter to Malaya, while others are also recorded in Australia and New Zealand. The so-called "oaks" of Australia are Casuarina, which also occurs in New Caledonia, but is wanting in New Zealand. The giant rushes Xanthorrhoea and Kingia are peculiar to New Zealand; but the others are of an Indo-Malayan type. Amongst Conifers, Podocarpus is found throughout; Agathis is common to Australia, New Zealand and New Caledonia; Araucaria to the first and last. Of Cycads, Anisocoma is found in New Zealand, and Borneo; Macrozamia and Bowenia. The Australian land-surface must be of great antiquity, possibly Jurassic, and its isolation scarcely less ancient. In Lower Eocene times its flora appears to have been distinctly related to the existing one. Little confidence can, however, be placed in the identification of Proteaceae or, indeed, of any distinctively Australian plants in Tertiary deposits in the northern hemisphere. The flora of South Africa and of the northern tropics; such exists on Kinnabalu in Borneo under the equator. The Proteaceous genus Helicia reaches as far north as China, but whether it is starting or returning must be in other cases be left an open question.

While the flora of New Caledonia is rich in species (3000), that of New Zealand is poor (1400). While so many conspicuous Australian elements are wanting in New Zealand, one-eighth of the flora belongs to the genera which are peculiar to the South African flora. Acaena, Gunnera, Fuchsia and Colcothara. By the same path it has received a remarkable contribution from the North Temperate region; such familiar genera as Ranunculus, Epipactis and Veronica form more than 9% of the flowering plants. It is interesting to note that while the tropical forms of Quercus failed to reach Australia from Malaya, the temperate Fagus crept in by a back door. Three quarters of the native species are endemic; they seem to be quite unable to resist the invasion of new-comers, and already 600 plants of foreign origin have succeeded in establishing themselves. 3. The Andine sub-region extends from Peru to the Argentine, and follows the path of communication between the northern and southern hemispheres which has always been more or less open, and the temperate flora of southern America does not exhibit the isolation characteristic of the regions of the northern tropics. Taking, however, the Andean flora as typical, it contains a very marked endemic element; Ball finds that half the genera and four-fifths of the species are limited to it; on the other hand, that half the species of the world are endemic. Amongst the most important are the molle, Genista, Barisia and Giphaphilus. The relation to the other sub-regions is slight. Ericaceae are wholly absent, and it has but a single Euphris in Fuegia. Proteaceae are more marked in Guastera and Hakea than in Protea. Cactaceae are absent, but have been introduced into Chile by Trichocereus and Thaliana. Tropaeolum takes the place of the nearly allied South African Pelargonium. There has been an interchange between it and the Mexican-American sub-region, and as usual the northern has been preponderant. Prostias extends to the Argentine; other characteristic genera are Oenothera, Godetia Collomia, Heliotropeum and Erithrichum. In the ascending stream may be mentioned—Larrea, a small genus of Zygophyllaeae with the species Larrea tridentata, the creosote plant of the Colorado desert, where it forms dense scrub; Acaena; the Loasaceae, of which Mentzelia reaches North America, Petunia and Lippia. Compositeae compose some 7% of the flora, which is a greater proportion than in any in the world. Baccharis, with some 250 species, ranges over the whole continent from the Straits of Magellan and, with seven species, to California. Melastomaceae, copiously represented in tropical America, are found in the same region of Chile southwards and extend to New Zealand and Tasmania. The Magnoliaceous genus Drimys, with a single species in the new-world, follows the same track. Bromeliaceae are represented by Rhodestachys and the temperate Isotoma. Palms, being few and not nearly related, are very abundant. Wettinia occurs in Peru, Trikrinx in Chile with the monotypic Jubaea, Juania, also monotypic, is confined to Juan Fernandez. Amongst Coniferae Podocarpus is common to this and preceding sub-regions; Libocedrus extends from California to New Zealand and New Caledonia; Fitzroya is found in Chile and Tasmania; and Araucaria in its most familiar species occurs in Chile.

Such a summary of the salient facts in the geographical distribution of plants sufficiently indicates the tangled fabric of the earth's existing floral covering. Its complexity reflects the corresponding intricacy of geographical and geological evolution. If the surface of the globe had been symmetrically divided into equal land, and these had been distributed in bands bounded by parallels of latitude, the character of vegetation would depend on temperature alone; and as regards its aggregate mass, we should find it attaining its maximum at the equator and sinking to its minimum at the poles. Under such circumstances the earth's vegetation would be very different from what it is, and as a result of population distribution would be a simple affair.

It is true that the earth's physical geography presents certain broad features to which plants are adapted. But within these there is the greatest local diversity of moisture, elevation and isolation. Plants can only exist, as Darwin has said, where they must, not where they can. New Zealand was poorly stocked with a weak flora; the more robust and aggressive one of the north temperate region was ready at any moment to invade it, but was held back by physical barriers which human aid has alone enabled it to surpass.

Palaeontological evidence conclusively proves that the surface of the earth has been successively occupied by vegetative forms of increasing complexity, rising from the simplest algae to the most highly organized flowering plant. We find the ultimate explanation of this in the facts that all organisms vary, and that their variations are inherited and, if useful, perpetuated. Structural complexity is brought about by the superposition of new variations on preceding ones. Continued existence implies a partial survival of each new form, and as such a species is no longer subjected to isolation and adjustment becomes more refined, the corresponding structural organization becomes more elaborate. Inheritance preserves what exists, and this can only be modified and added to. Thus Asclepiadeae and Orchidaceae owe their extraordinary florid complexity to adaptation to insect fertilization.

All organisms, then, are closely adapted to their surroundings. If these change, as we know they have changed, the organisms must change too, or perish. In some cases they survive by migration, but this is only possible by prohibited barriers.
These, however, have often protected them from the competition of more vigorous invading races. Fagus, starting from the northern hemisphere, has more than held its own in Europe and Asia, but has all but died out in North America, finding conditions favourable for a fresh start in Australasia. The older types of Gymnosperms are inelastic and dying out. Even Pinus has found the task of crossing the tropics insuperable.

The whole story points to a general distribution of flowering plants from the northern hemisphere southwards. It confirms the general belief on geological grounds that this was the seat of their development at the close of the Mesozoic era. It is certain that they originally existed under warmer conditions of climate than now obtain, and that progressive refrigeration has supplied a powerful impulse to migration. The tropics eventually became, what they are now, great areas of preservation. The Northern Temperate region was denuded of its floral wealth, of which it only retains a comparatively scanty wreck. High mountain levels supplied paths of communication for stocking the South Temperate region, the floras of which were enriched by adapted forms of tropical types. Such profound changes must necessarily have been accompanied by a corresponding change in the mental life of the people, the traditions of the ancients being thinned out by falling out on the way. Further development, however, not stopped, but in many cases stimulated by migration and settlement in new homes. The northern Quercus, arrested at the tropic in the new world, expanded in that of the old into new and striking races. And it cannot be doubted that the profusion of Melastomeae in South America was not derived from elsewhere, but the result of local evolution. There is some evidence of a returning stream from the south, but as Hooker and A. de Candolle have pointed out, it is insignificant as compared with the outgoing one. Darwin attributes this to the fact that "the northern forms were the more powerful" (Origin of Species, 5th ed., p. 458).

The result of migration is that races of widely different origin and habitat have had to adapt themselves to similar conditions. This has brought about superficial resemblance in the floras of different countries. At first sight a South African Euphorbia might be mistaken for a South American Cactus, an Aloe for an Agave, a Senecio for ivy, or a New Zealand Veronica for a European Salicaria. A geographical botany based on such resemblances is only in reality a study of adaptations. The investigation of these may raise and solve interesting physiological problems, but throw no light on the facts and genetic relationship which a rational explanation of distribution requires. If we adopt a study of a population and sort it merely according to zoologists, and may thereby be presumed to be on the whole "natural.

PLANUNDUS, MAXIMUS (c. 1260–1330), Byzantine grammarian and theologian, flourished during the reigns of Michael VIII. and Andronicus II. Palaeologo. He was born at Nicomedia in Bithynia, but the greater part of his life was spent in Constantinople, where as a monk he devoted himself to study and teaching. On entering the monastery he changed his original name Manuel to Maximus. Planudes possessed a knowledge of Latin remarkable at a time when Rome and Italy were regarded with hatred and contempt by the Byzantines. To this accomplishment he probably owed his selection as one of the ambassadors sent by Andronicus II. in 1327 to demonstrate with the Venetians for their attack upon the Genoese settlement in Pera. A more important result was that Planudes, especially by his translations, paved the way for the introduction of the Greek language and literature into the West.

He was the author of numerous works; notably a Greek grammar in the form of questions and answers, the "Clavices of Moschopulius" with an appendix on the so-called "political" verse; a treatise on syntax; a biography of Aesop and a prose version of the fables; two hexameter poems, one a eulogy of Claudius Prolemus, and the other an account of the genesis of an ox into a mouse; a treatise on the method of calculating in use amongst the Indians (ed. C. J. Gerhardt, Halle, 1865); and scholia to the first two books of the "Arithmetical of Diophantus." His numerous translations from the Latin included Cicero's Somnium Scipionis with the commentary of Macrobius: Caesar's Gallic War; Ovid's Heroides and Metamorphoses; Boethius, De consolatione philosophiae; Augustine, De trinitate. These translations were very popular during the middle ages as textbooks for the study of Greek. It is, however, as the editor and compiler of the collection of minor poems known by his name (see ANTHOLOGY: Greek) that he is chiefly remembered.

See Fabricius, Bibliotheca graeca, ed. Harles, xi. 682; theological writings in Migne, Patrologia graeca, exxvi; correspondence, ed. F. Rivoallon, 1869; various modern commentaries: K. Krumbacker, Geschichte der byzantinischen Literatur (1897); J. E. Sandy, Hist. of Class. Schol. (1906), vol. i.

PLAQUE, a French term for a small flat plate or tablet, applied particularly to rectangular or circular ornamental plates or tablets of bronze, silver, lead or other metal, or of porcelain or ivory. Small plaques, plaquettes, in low relief in bronze or lead, were produced in great perfection in Italy at the end of the 15th and beginning of the 16th centuries, and have ever since, but on a smaller scale, been the delight of antiquaries. The plaques of ancient engraved gems, earlier goldsmiths and the like.

PLASENCIA, a city of Spain and an episcopal see, in the north of the province of Caceres. Pop. (1890), 8208. Plasencia is situated on the river Jerte, a tributary of the Tagus, and at the foot of the sierras of Bejar and Vera. The place has some interest on account of its fine walls, built in 1197 by Alphonso VIII. of Castile, and its cathedral, begun in 1498, a favourable specimen of the ornate Gothic of its period. The Hieronymite convent of Yuste, the scene of the last years of the emperor Charles V. (1550–1558), is 24 m. east.

PLASSEY (Palas), a village of Bengal on the river Bhagirathi, on the form scene of the celebrated battle of 1757, on June 23rd, over the forces of the nawab Siraj-ud-Dowlah. The fall of Calcutta and the "Black Hole" atrocity led to instant action by the East India Company, and Clive, with as many troops as could be spared, undertook a campaign against the nawab, and soon reoccupied Calcutta. Long and intricate negotiations, or rather intrigues, followed, and at the time of the battle the loyalty of most of the nawab's generals had been effectually undermined, though assistance, active or passive, could hardly be counted on. With this doubtful advantage, Clive, with 1100 European and 2100 native soldiers, and 10 field-pieces, took the field against the nawab, who had 50,000 to 60,000 men, 53 heavy guns, and some French artillery under M. de St. Frains. Only the river Bhagirathi separated Clive's little force from the entrenched camp of the enemy, when the English leader, for once undecided, called a council of war. Clive and the majority were against fighting, Major Eyre Coote, of the 39th Foot, and a few others for action. Coote's solderly advice powerfully impressed Clive, and after deep consideration he altered his mind and issued orders to cross the river. After a fatigue march, the force bivouacked in a grove near Plassey early on the 23rd. The nawab's host came out of its lines and was drawn up in a huge semicircle almost enclosing the little force in the grove, and St Frains' gunners on the right wing opened fire. Clive replied, and was soon subjected to the converging fire of 50 heavy guns. For hours the unequal fight was maintained,
until a rainstorm stopped it. The English covered up their guns, but the enemy took no such precaution. Mir Musin, the only loyal general in the army, being afraid that his guns would be as useless as his own, made a dash in a cavalry charge upon them; he lost his own life, and his colleagues then had the game in their hands. Mir Jarag persuaded the nawab to retire into the entrenchments. St. Fras stood fast until one of Clive’s officers, Major Kilpatrick, successfully drove him in. Clive followed up this success by cannoneading the camp at close range. But the rank and file of the native army, ignorant of the treachery of their leaders, made a furious sortie. For a time Clive was hard pressed, but his cool generalship held its own against the undisciplined valour of the enemy, and, noticing Mir Jarag’s division in his rear made no move against it. But when his troops straight against the work. After a short resistance, made chiefly by St. Fras, the whole camp fell into his hands. At a cost of 23 killed and 40 wounded this day’s work decided the fate of Bengal. The historic grove of mangoes, in which Clive encamped on the previous night, has been entirely washed away by changes in the course of the river; but other relics of the day remain, and a monument has recently been erected.

PLASTER, a mixture of lime, hair and sand, used to cover rough walling of lathwork between timbers (see PLASTERWORK); also a fine white plaster of gypsum, generally known as “plaster of Paris.” The word (also as “plaster”) is used in medicine of adhesive mixtures, or as an external dressing for the protection of injured surfaces, for support of weak muscular or other structures, or as counter-irritants, soothing applications &c. The ultimate derivation of the word is the Gr. εμπλαστην or εμπλαστων in the medical sense, from επι, on, and πλαστευω, to daub or smear.

PLASTER OF PARIS, a variety of calcined gypsum (calcium sulphate) which forms a hard cement when treated with water (see CEMENT). The substance obtained its name in consequence of being largely manufactured in the neighbourhood of Paris.

PLASTER-WORK, in building. Plastering is one of the most ancient of handicrafts employed in connexion with building operations, the earliest evidence showing that the dwellings of primitive man were erected in a simple fashion with sticks and plastered with mud. Soon a more lasting and sightly material was found and employed to take the place of mud or slime, and that perfection in the compounding of plastering materials was approached at a very remote period is made evident by the fact that some of the earliest plastering which has remained undisturbed excels in its scientific composition that which we use at the present day. The pyramids in Egypt contain plaster-work executed at least four thousand years ago (probably much earlier) and yet existing, hard and durable, at the present time. From recent discoveries it has been ascertained that the principal tools of the plasterer of that time were practically identical in design, shape and purpose with those used to-day. For their finest work the Egyptians used a plaster made from calcined gypsum just like the “plaster of Paris” of the present time, and their methods of plastering on reeds resemble in every way our “lath, plaster, float and set” work. Hair was introduced to strengthen the “stuff,” and the whole finished somewhat under an inch thick. Very early in the history of Greek architecture we find the use of plaster of a fine white stucco. Such has been found at Mycenae. The art had reached perfection in Greece more than five centuries before Christ, and plaster was frequently used to cover temples externally and internally, in some cases even where the building was of marble. It formed a splendid ground for decorative painting, which at this period of Greek history had reached a very high degree of beauty. The temple of Apollo at Bassae, built of yellow sandstone about 470 B.C., is an excellent example. Pavements of thick, hard plaster, stained with various pigments, were commonly laid in Greek temples. The Roman architect Vitruvius, in his book on architecture written about 16 B.C., gives detailed information concerning the methods of making plaster and the manner of using it. “The lime used for stucco,” he writes, “should be of the best quality and tempered a long time before it is wanted for use. The Greeks, besides making their stucco with thin water, but thick dust plaster polished with chalk or marble, caused the plaster to be beaten with wooden staves by a great number of men. Some persons cutting slabs of such plaster from ancient walls use them for tables and mirrors.” Pliny the elder tells us that “no builder should employ lime which had not been slaked at least three years,” and that “the Greeks used to grind their lime very fine and beat it with pestles of wood.” In England the walls of large houses and mansions were formerly plastered above the wainscotting and coloured, while the ornamented plaster ceilings of the time of Henry VIII., Elizabeth and James I., are still the admiration of lovers of the art. Still earlier examples of a kind of plaster were used in the decorated and ornamented fronts of half-timbered houses. With regard to the smaller buildings, comprising small dwelling-houses and cottages, the general application of plaster is of comparatively late date; for wainscoted walls and boarded ceilings or naked joints alone are frequently found in houses of not more than a century old both in England and on the Continent.

In the more common operations of plastering, comparatively few tools and few materials are required, but the workman efficient in all branches of the craft will possess a very large variety of implements. The materials of the workman are lime, sand, hair, plaster, of Paris, and a variety of cements, together with various ingredients to form colourings, &c.

Wood laths are narrow strips of some straight-grained wood, generally Baltic or American fir, in lengths of from two to four or five feet to suit the distances at which the timbers of a floor or partition are set. Laths are about 2 in. wide, and are made in three thicknesses; “single” (1 in. thick), “lath and a half” (1½ in. thick), and “double” (1⅓ in. thick). The laths are nailed to the ceiling boards, in the line of the latter which will be subjected to rough usage, in which case thicker laths become necessary. Laths are usually nailed with a nail about 3 in. long and furnished with a key for the plaster. Laths were formerly all made by hand. A large quantity, however, are now made by machinery and are known as sawn laths, those made by hand being called rent or riven laths. Rent laths give the best results, as they split in a line with the grain of the wood, and are stronger and not so liable to twist as machine-made laths, some of the hires of which are usually cut in the process of sawing. Laths must be nailed so as to break joint in two or four feet wide strips, and be set flat against each other. The breaking of the lathing in this way, the tendency for the plaster to crack along the line of joints is diminished and a better key is obtained. Every lath should be nailed at each end and wherever it crosses a stud.

All the laths should be perfectly straight and lathed, that is, have a fillet or double lath nailed along the centre upon which the laths are then nailed. This is done to preserve a half lath for the upper course and to make the lime liable to damp are sometimes battened and lathed in order to form an air cavity between the damp wall and the plastering.

Lathing of metal, either of wire or in the form of perforated sheets, is now extensively used on account of its fire-proof and lasting quality. There are very many kinds of this material made in different designs under various patents, the best-known in England being the Jhililin, the Bostwick, and the Exposed Metal lathing. The two last-named are also widely used in America.

Lathing nails are usually of iron, cut, wrought or cast—and in the better class of work they are galvanized to prevent rusting. Zinc nails are sometimes used.

Limes. The lime principally used for internal plastering is that calcined from chalk or other nearly pure limestone, and is known as fat, pure, or rich lime. Hydraulic limes, which are referred to in the articles BRICKWORK and MORTAR, are also used by the plasterer, chiefly for external work. Perfect slaking of the calcined lime before being used is very important. After a period of time a part of the lime has crystallised in position and the plasterer is not only in the lime should therefore be run as soon as the building is begun, and at least three weeks should elapse between the operation of running the lime and its use.

Hair. Nothing used in plastering gives more tenacity to the material. Ox-hair, which is sold in three qualities, is the kind usually specified; but horsehair, which is shorter, is sometimes substituted in its stead or mixed with the ox-hair in the lower qualities. Good hair should be long, strong, and free from grease and dirt, and before use must be well beaten to separate the lumps. In America, goats’ hair is frequently used.
though it is not so strong as ox-hair. The quantity used in good plaster-work is one pound of hair to two or three cubic feet of coarse stuff.

Manila hemp fibre has been used as a substitute for hair. As a result of experiments to ascertain its strength as compared with horsehair, it was found that of other shreds and slabs made with Manila hemp fibre broke at 15 lb., plaster mixed with Sisal hemp at 160 lb., jute at 145 lb., and goats' hair at 90 lb. An ordinary mix is made in the following manner. Two barrels of mortar were made up of equal proportions of lime and sand, one containing the usual quantity of goats' hair, and the other Manila fibre. After remaining in a dry cellar for nine months, the samples were tested to find that the hair had been almost entirely eaten away by the action of the lime, and the mortar consequently broke up and crumbled quite easily. Two coats containing the Manila hemp, on the other hand, showed great cohesion, the surface being hard and smooth, the fibre being apparently quite unjuiced. Sawdust has been used as a substitute for hair and also instead of sand as an aggregate. It is useful sometimes for decorative corners, and when used as it renders the material light and strong. The sawdust should be used dry.

Some remarks are made on the ordinary sands for building in the articles on Brickwork and Mortar. For fine plasterer's work special sands, not hitherto referred to, are used, such as silver sand, which is used when a light colour and fine texture are required. Instead of this fine white sand is procured chiefly from Leighton Buzzard.

For external work Portland cement is undoubtedly the best material on account of its strength, durability, and weather-resisting properties. Portland cement and lime and sand is the best rendering for external work in modern buildings.

Stucco. 

The opening of the 19th century a great deal of this work was done. The principal varieties of stucco are common, rough, trowelled and heavy Portland cement, and lime and sand, and is largely superseded. Lime and sand stucco for external work is usually composed of one part hydraulic lime and three parts sand. The wall should be sufficiently rough to form a key and well wetted to prevent the moisture being absorbed by the stucco.

Rough stucco is used to imitate stonework. It is worked with a hand float covered with rough felt, which forms a sand surface on the plaster. Lines are ruled before the stuff is set to represent the joints of stonework. Trowelled stucco, the finishing coat of this work, consists of three parts sand to two parts fine stuff. A very fine smooth surface is produced by means of the hand float. Bastard stucco is of similar composition, but less labour is expended on it. The first coat is spread on as coarse as possible, then allowed to set at once, and then trowelled. Coloured stucco: lime stucco may be executed in colours, the desired tints being obtained by mixing with the lime various vegetable pigments. Bluish tints are obtainable by the use of ultramarine, in varying proportions, greens by green enamel, reds by using litharge or red lead, and blues by mixing oxide or carbonate of copper with the other materials.

The "filling in," or "flanking," consists of laying the spaces between the screebs with coarse stuff, which is brought flush with the level of the surface with the floating float. The "floating" of the filling is one of the chief points of skill, for it consolitates the material, and, besides hardening it, prevents it from cracking. It is done by the plasterer with a hand float and a trowel, as follows: the place to be filled is skinned or pulled away, the walls are plane and floated and the cut screebs levelled. Screebs are narrow strips of plastering, carefully plumbed and levelled, so as to form a guide upon which the floating flat or run, securing a perfectly horizontal or vertical surface, or, as in the case of circular work, a uniform curve.

The "filling in," or "flanking," consists of laying the spaces between the screebs with coarse stuff, which is brought flush with the level of the surface with the floating float. The "floating" of the filling is one of the chief points of skill, for it consolidates the material, and, besides hardening it, prevents it from cracking. It is done by the plasterer with a hand float and a trowel, as follows: the place to be filled is skinned or pulled away, the walls are plane and floated and the cut screebs levelled. Screebs are narrow strips of plastering, carefully plumbed and levelled, so as to form a guide upon which the floating float runs, securing a perfectly horizontal or vertical surface, or, as in the case of circular work, a uniform curve.

The "floating" of the filling is one of the chief points of skill, for it consolidates the material, and, besides hardening it, prevents it from cracking. It is done by the plasterer with a hand float and a trowel, as follows:

The third and final coat is the "setting coat," which should be about 1 in. thick. In Scotland it is termed "harling." It is one of the oldest forms of external plastering. In Tudor times it was employed to fill in between the woodwork of half-timbered framing. When well executed with good material this kind of plastering is very durable. Roughcasting is performed by first rendering the wall or laths with a coat of well-hair red Portland cement, composed of eight parts of Portland cement and one part of lime, to a depth of about 1 in. and then floated or plastered with a trowel to a thickness of about 1 in. and floated to the desired level. The second coat should be floated, not more than 1 in. thick, and the finishing coat, which is also composed of coarse stuff knocked up to a smooth and uniform consistency. While this coat is still soft, gravel, shingle or small stones are evenly thrown on while dry and then floated and brushed over with lime mortar to give a uniform surface. The shingle is often dipped in hot lime paste, well stirred up, and used as required. Sgrafitto (Italian for "scratched") is a relief ornament in plaster work. It is the oldest form of surface decoration, and at the present day it is much used on the continent of Europe, especially in Germany and Italy, in both external and internal situations. The process is carried out in this way: A first coat or rendering of Portland cement and sand, in the proportion of one to three, is laid on about 1 in. thick; then follows the colour coat, often called the patch coat, consisting of the same materials, but ground to a powder. The mixture is then applied for the finished design. When this coat is nearly dry, it is finished with a smooth-skimming, 1/8 in. thick, of Parian, selenitic or other fine cement or lime, only as much as can be finished in one day being laid on. Then by pouring water over the surface and brushing it, the design is transferred to the plastered surface. Broad spaces of background are now exposed by removing the finishing coat, and the design is then traced with the trowel beneath, and, following this the outline of the rest of the design is traced through the outer skimming to the underlying tinted surface. Sometimes the coats are in three different colours, such as brown for the design, and white and black for the finishing coat.

The pigments used for this work include Indian red, Turkey red, Antwerp blue, German blue, ochre, purple brown, bone black or oxide of manganese for black. Combinations of these colours are made to produce all intermediate shades.

Lime plastering is composed of lime, sand, hair and water in proportions varying according to the nature of the work to be done. For the best cases of rich materials, well mixed and skillfully applied, a coating is required of 3 in. to 3½ in. thick. This is applied in successive coats or layers on walls or lintels, and gains its name from the number of these coats. One coat is usually the smoothest, and is composed of a three-layers of material, and is described as "render" or "in." A second coat, consisting of three layers of material, is described as "render," "in," and "set," or "lath, plaster and set," or "lath, lay and set" on laths.

The first coat is a layer of well-hairred coarse stuff, about 1 in. thick, is put on with the laying trowel. This is termed "pricking up" in London, and in America "scratch coating." It should be worked on directly after being dry and coarse. The second coat is often used for factories or warehouses, and the less important rooms of the house. The second coat is a layer of well-hairred coarse stuff, about 1 in. thick, is put on with the laying trowel. This is termed "pricking up" in London, and in America "scratch coating." PLATA, RIO DE LA

stuff, or lime putty, is pure lime which has been slaked and then mixed with water to form a mass which sets when dry. It also developed into a soft paste. For use in setting is mixed with fine washed sand in the ratio of one to three.

For cornices and for setting when the second coat is not allowed time to dry, or when special compound is to be used, this is often “gauged” stuff, composed of three or four parts of lime putty and one part of plaster of Paris, mixed up in small quantities immediately before use. The plaster in the material causes it to set rapidly, but if it is present in too large a proportion the work will crack in setting.

The hard cements used for plastering, such as Parian, Keene’s, and Martin’s, are laid generally in two coats, the first being allowed to dry before the second. For setting coat or setting coat of neat cement about ¹⁄₂ in. thick. These and similar cements have a gypseous base, to which a certain proportion of another substance, such as alum, borax or carbo-sulphuric, is added when the workman gauges the composition at his own temperature. The plaster they contain causes them to set quickly with a very hard smooth surface, which may be papered or painted within a few hours of its being finished.

The principle books of reference on the subject are: W. Millar, Plastering, Painting and Papering (1847); R. Belleni, Limes, Cement, Mortar and Mastics; Rivington, Notes on Building Construction, Part III, “Building Materials”; the works on architecture of Robert and James Adam. (J. Br.)

PLATA, RIO DE LA, or RIVER PLATE, a funnel-shaped estuary, on the east side of South America, extending W.N.W. from the sea about 170 m. The discovery of the South Sea by Balboa, then governor of Castilla del Oro, of which Darin peninsula, created a lively desire to learn something of its coast-line, and the year following (1524), the Spanish monarch concluded a navigation contract with Juan Diaz de Solis, then Piloto Mayor, to search for a strait connecting the Atlantic with the newly found ocean, explore the coasts of the latter and communicate with Pedrarias de Avila, the new governor of Castilla del Oro; and, if it were found to be an island, to report to the superior authorities, of Cuba. De Solis set sail from the port of Lepe on the 8th of October 1535, reached the Bay of Rio de Janeiro on the 1st of January 1536, and continuing southward to lat. 35° entered the great estuary now known as the Plata, which, for a short period of time, was called the de Solis, and the Mar del Plata. The estuary, the vicinity of the island of Martin Garcia, near the mouth of the Parana river, de Solis was ambushed and killed in the early part of 1536 by Guarani Indians while attempting to capture some of them.

In the first months of 1530 Magellan explored the Rio de la Plata, and afterwards, in the same year, discovered and navigated the straits which bear his name. This discovery led to the voyage of Sebastian Cabot, which fitted out an expedition in 1536 to reach the Spice Islands by the Magellan route. Owning, however, to shortness of provisions and the insubordination of his men Cabot abandoned his proposed voyage to the Moluccas, and, ascending the Mar Dulce, discovered the Parana river and reached a point on the Paraguay near Montevideo, the present city of Asuncion. Here he met many Guarani Indians wearing silver ornaments, probably obtained in trade across the Gran Chaco, from the frontier of the Inca Empire. In exchange for beads and trinkets Cabot acquired many of these ornaments and sent them to Spain as evidence of the richness of the country in precious metals and the great importance of his discoveries.

The receipt of these silver baubles caused the name of Rio de la Plata to be applied to the third (perhaps the second) greatest river of the Western Continent.

The extreme breadth of the river at its mouth is 136 m. It narrows quickly to 57 m. at Montevideo, and at its head, where it receives the united Parana and Uruguay rivers, its width is 164 m. Its basin contains about 2,500,000 sq. m., the Uruguayan coastal strip is very elevated and rocky, while the southern or Buenos Aires region is very low. The whole estuary is very shallow, and in no place above Montevideo exceeds 36 ft. in depth when the river is low.

The bottom generally consists of enormous banks of sand covered with from 10 to 20 ft. of water, and there is a continuous and intricate channel, of about 22 ft. depth only, to within 14 m. of the port of Buenos Aires. The remaining distance has a depth of 13 ft. in the uncertain channel. The Plata is simply the estuarine receptacle of two mighty streams, the Uruguay and Parana, which drain the Plata basin. This has an area of 1,198,000 sq. m., or over two and one-half times that of the Pacific slope of the Andes, and contains the most fertile, healthiest and best part of Brazil, a large portion of the Argentine Republic, the whole of Paraguay and south-eastern Bolivia, and most of Uruguay.

The Uruguay river has a length of about 1000 m. Many small streams from the western slope of the Brazilian Serra do Mar unite, in about 27° 45' S., to form this river, which then flows W.N.W., serving as the boundary between the state of Santa Catarina and Rio Grande do Sul, as far as 59° W., near which it receives a considerable tributary from the north, called the Pepiri-gauz.

Between 27° 38' and 33° 54' S. three important tributaries join it from the east—the Itu-gauz, the Ibiene and the Negro, the last being its main affluent.
The Paraná-guazú was one of the limits between the possessions of Portugal and Spain. Its lower course is about 250 ft. wide, but higher up it narrows to about 30 ft., and runs with great violence between high wooded banks. It is navigable for canoes for about 20 miles, but above this point the delta of several large islands at its confluence with the Uruguay its head-waters are in the southern port of Rio Grande do Sul, but the main river belongs entirely to the state of Uruguay, which it forms from its source. East, long a navigable water body, its waters into a single volume, to plunge with frightful velocity through a long cataract only about 200 ft. wide. From these so-called falls of Guairá, the Paraná-guazú plunges down 600 ft., and 9 miles wide, is wide as far down to a size of 70 ft. wide and from 10 to 40 ft. deep. The Uruguay is much obstructed by rocky barriers. Four miles below its confluence with the Paraná-guazú it has a cataract, about 8 m. long, with a total fall of 26 ft. at low water. The river near the Paraná-guazú is 1500 ft. wide, but about 1 m. before reaching the cataract its width is reduced to 600 ft. The river runs here through high precipitous cliffs of black rock only 79 ft. apart. Above Punta Gorda, which is the Salto Grande, which has a length of 15 m. of rapid, the greatest single fall being 12 ft., and the difference of level for the entire length of the fall is nearly 10 m. The Paraná-guazú consists of several falls, each with a length of 1 m. of them, are submerging. Nine miles below the Salto Grande is the Salto Chico, which has navigation during six months of the year, but in flood-time may be passed in ord. The Paraná-guazú, and is nearly 2 miles wide, and can navigate for many hundreds of miles upon the main artery and its branches, between the rapids which are met with from time to time. The Uruguay has its annual flood beginning at the end of July and continues to November, attaining their maximum during September and October. At the narrow place the river rises as high as 30 ft., but its average rise is only 2 ft. The Paraná-guazú begins to walk down a bed of open sandstone, at times very coarse and then again of extremely fine composition. Except in floods, it is a clear-water stream, and even at its highest level carries comparatively little water.

The Paraná (the "Mother of the Sea" in Guarani) drains a vast area of southern Brazil. It is formed by the union of the Rio Grande and Paraná-Parahyba, and is about 1600 m. long from its source. From the point where the Paraná flows into the Paraguay, and thence more to the Plata estuary. Its average width for the latter length is from 1 to 3 m. Its Rio Grande branch belongs, however, to the right and left of the Uruguay in the state of Misiones, where the orographic system of Brazil culminates near the peak of Itatiaia-and, almost in sight of Rio de Janeiro. It is about 680 m. long, but is navigable in the stretch between the cataracts for several hundred miles, and its waters range from 80 to 120 ft. wide, reaching the drainage of the southern slopes of the Chiquitos sierras, but represent mainly the south-west overflow of the vast morass of Xarayas. The principal of these lakes, naming them from north to south, are the Ubarba, the Gaia, Mandioré and the "Babia" or Caceres. The Ubarba is the largest. The northern division of the lake belongs entirely to Brazil, but the southern one, 150 miles in length, forms the boundary line between Brazil and Bolivia, according to the treaty of 1867. It is in great part surrounded by high ground and hills, but its southern canal, parallel to the city of Monte Grande, which is on the frontier of the empire of the Incas. At the Puerto de los Reyes Bolivia laid out a town in December 1900, in the fortorn hope that the "Fort" might serve as an outlet for that commercially suffocated river. It is the site of one of the equally good accessible points for Bolivia on the Paraná River.

South of the São Lourenço, the first river of importance which enters the Paraguay from the east is the "Taytay," about 95 m. wide and about 150 m. long, which forms the boundary line of the Matto Grosso table-land. South of this stream is about 50 m. a considerable river, the Monegro, with many branches, draining a great expanse of country. South of the Matto Grosso, also flows into the Paraguay; and still farther south, near 21°, is the Apírè, which forms the boundary Paraguay and Brazilian Matto Grosso.
PLATA, RIO DE LA

The Pilcomayo is of more importance from its length than from its volume. It rises among the Bolivian Andes north of Potosí and north-west of Sucre, runs down the mountains to their base, crosses the Chaco plains, and pours into the Paraguay near Salta. Nor does it waste a branch of importance until it reaches about 21° S., where it is joined from the south-west by the river Pelaya, upon which Tupiza, the most southerly city of Bolivia, is situated. The Pelaya rises upon the plateau of the Salteñas, in its course to the south-east across the inland Andean range, turns northwards and then eastwards to unite with the Pilcomayo, which it is said at least to equal in volume. Just below the junction is the fall of Guaranás, an elevation of 206 ft. to this point at the mouth of the river, and the distance in a straight line is 480 m., although by the curves of the river, which is extremely tortuous, it is about double that distance. Thence, with a fall of 21° 51' S., but again becomes a single stream at 23° 43', the right channel being the greater in volume. It is probable that between 23° and 24° S. it throws E.S.E. three great arms to the right, around the head-forests, which are to be explored, but the lower parts have been examined for 100 to 200 m. up from the Paraguay. Enumerating from north to south, they are called the Esperanza, the Montelindo and the Mack. From 180 to 200 m. and the Argentine city of Jujuy. Its thoroughfare is about 100 m. in diameter, through which there is no principal channel. This channel, or perhaps shallow lagoon, is probably partly drained by the river Códoba, which reaches the Paraguay between the Pilcomayo and the Uruguay. A noted island, called the Fontana, the junction being at 22° 36' S., is probably also a drainage outlet of the same great stream.

For the first 100 m. below the mouth of the Paraguay, the Pilcomayo is wide and shallow, but it so distributes its waters through a multitude of channels and losses so much from evaporation and discharge that the stream is not so large as the Montelindo, the section that is before it reaches the Paraguay. From Sucre to the Andean margin of the Chaco, a distance of about 350 m. by the river, the fall is at least 8000 ft.—a sufficient indication that its upper course is useless for purposes of navigation.

The missionaries in 1556 reported the existence of the Pilcomayo, which for a long period of time was known as the Aragüey. In 1721 Patiño and Rodriguez partially explored it, and since then numerous attempts have been made to cross the region which has been failures; and several of them have ended in disaster and loss of life, so that the Pilcomayo now has a sinister reputation.

The Bermejo river flows parallel to the Pilcomayo and the Paraguay, a few miles north of the junction of these two rivers. Its numerous sources are on the eastern front of the inland Andes, between the Bolivian town of Tarjía and the Argentine city of Jujuy. Its thoroughfare is the San Lorenzo, which, after being augmented by several small streams, takes the name of Rio de Tarjía. Running east, and then taking a general south-easterly course, it joins the Bermejo and Uruguay at 25° 30' S., where it receives most of its tributaries. Thence, flying southwards, the Bermejo finally, in 23° 50' S., receives its main affluent, the San Francisco, from the west-south-west. The latter has its source in about 22° 30' S., and, under the name of Rio Güipúzcoa, flows north-westwards, receiving the Tanquil, of which the principal head-waters are the Guaycura, as Jujuy. It then turns eastwards for 50 m., and is joined by the Layaén from the south-west. These two streams form the San Francisco, which, from their junction, runs north-eastwards to the town of the same name, 24° 11' S. and 64° 48' W.; it is seldom over 2 ft. deep, and has many shales and sandbanks. From its junction with the latter stream the Bermejo flows south-eastwards to the Paraguay with an average width in its main channel of about 600 ft., although narrowing at times to 100 ft. and even 100. In its course, however, it bifurcates and ramifies into many channels, forming enormous islands, and frequently leaves off altogether.

Since the exploration of the Bermejo by Patiño in 1721, it has often been examined from its sources to its mouth, with a view to ascertain its navigability. Captain Page in 1855 and 1859 found it navigable, although partly so, for 40 m., and over Aguilón where a little steamer drawing 23 in. of water; but in flood-time, in December 1871, he succeeded, in 60 days, in reaching a point 720 m. from its mouth, in the steamer "Alpha," 83 ft. long and 30 in. draught. He afterwards penetrated another 100 m. up stream. The round voyage took a year, owing to the swift currents, shoals, quicksands, snags and fallen trees.

The Salado, about 250 m. south-west of and approximately parallel to the Bermejo, is a great tributary which the Paraná receives from the west below its confluence with the Paraguay. Its extreme head-waters are in the Argentine province of Salta, and they drain a much broken Andean region lying between the east and the north-east, and the head-waters of the rivers Santa María and Calchaquí, which unite near the town of San Carlos and form the river Guachipas. Having received the Arhu, the Guachipas runs north-eastwards for about 100 m., and then it changes its name to the Juramento, which is retained until the river reaches the Chaco plains at the base of the foot-hills of the Andes.

Here it becomes the Salado, a name it preserves for the remainder of its course. It joins the Paraná near Santa Fé in 31° 39' south and 60° 41' west. Explorers of the Salado, inclusive of Captain Page in 1855, claim that its lower half is navigable, but the many efforts which have been made to utilize it as a commercial route have all resulted in failure.

As the Pilcomayo, the Bermejo and the Salado wander about the country, ever in search of new channels, they clog and tear away the head-forests, their branches fan out and pour it into the Paraguay and Paraná rivers. The engineer Pellechi estimates that "the soil annually subtracted from the territory of the Chaco by the Bermejo alone equals 6,400,000 cubic yards of earth." The Paraná washes the western foot of a series of sandstone bluffs for 30 miles. Thence for 240 m. the bordering hills are about 80 ft. high, and at Goya the stream is 270 ft. wide, and parallels the river. The Paraná is so wide that it cannot be traversed without some means of propulsion. The Pilcomayo, which has been described as "a precipice of red clay," is unaided by any natural means of water conveyance. Below its junction with the Paraguay the Paraná has an average current of 22 ft. an hour, and the river varies in width from 1 to 5 m., at low water; but in floods it seems almost a continuous lake, broadening to 10 and 30 m. and burying many of its numerous islands and marginal swamps under a vast sheet of water, and obliterating its many parallel lateral channels and intricate systems of connecting canals.

In the middle Paraná, from the mouth of the Iguaçu to the mouth of the Paraguay river, there are many islands, some of them large, rocky and high above the river. From Paragüay to the mouth of the Rosario River there is a series of small islands of great area; and again below Rosario they soon increase in number and size until the Plata estuary is reached. In flood-time the upper portion of the trees being out of water, they have not an appearance of floating forest. Then the river often makes wild work with its banks, and builds up or sweeps away entire islands, leaving deep channels instead. Mouchez in 1857, searching for two islands the position of which he had fixed in the previous year, found them. In 1899, de Pellechi, and subsequently of the drawing is the first time it is so does not share in these phenomena; its islands and main channels appear more fixed. This probably is due to the less elevation attained by the islands on a course, and the numerous branches which flow through them, and this is the more remarkable in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraná affluent, and from the tributaries which and in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraná affluent, and from the tributaries which and in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraná affluent, and from the tributaries which and in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraná affluent, and from the tributaries which and in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraná affluent, and from the tributaries which...
PLATAEA—PLATE

those which lie to the south of the Plata, there was for the six years ending with 1899 an annual average of 14,000,000 tons for the overseas commerce and 11,000,000 tons for the river and coasting trade. On the other, or northern, bank of the stream the chief port is Montevideo; and its foreign commerce increased from an aggregate of 50,000 tons in 1822 to 150,000 tons in 1845 and to 400,000 in 1898, the river and coasting trade having increased from 50,000 tons in 1822 to 150,000 tons in 1845 and to 3,915,421 tons in 1898. The total foreign trade of the Plata, 500,000 tons, has increased from over 157,000 tons in 1822 to nearly 18,100,000 tons in 1898. Its growth since the opening of the 19th century has been phenomenal and its commerce is becoming gigantic. The Andes on the west, the interior of South America on the north, and the mountains on the east of the Plata basin are obstacles which compel the rich and varied products of at least 1,500,000 sq. m. of fertile country to seek access to the ocean by a single avenue—the Plata estuary.

PLATAEA, or PLATEA, an ancient Greek city of Boeotia, situated close under Mt Cithaeron, near the passes leading from Peloponnesus and Attica to Thebes, and separated from the latter city's territory by the river Asopus. Though one of the smallest Boeotian towns, it stubbornly resisted the centralizing policy of Thebes. In 519 B.C. it invoked Sparta's help against its powerful neighbour, but was referred by king Cleomenes to Athens (for the date, see Grote's History of Greece, ed. 1967, p. 82, note 4). The Athenians secured Plataea's independence and renewed its enduring friendship. In 490 the Plataeans sent their full levy to the assistance of the Athenians at Marathon, and during the Persian invasion of 480 B.C. joined eagerly in the national defence. At Artemisium they volunteered to man several Athenian ships, and subsequently abandoned their town to be burnt by Xerxes. In 470 they fought against the Persians under Mardonius in the decisive battle which bears the name of the city. In this campaign the Persian commander, retiring from Attica before the combined Peloponnesian and Athenian levy, had encamped in the Asopus plain in order to give battle on ground suited to his numerous cavalry. The Greeks under the Spartan regent Pausanias at first fought on the flanks of the Persian army, but, encouraged by successful skirmishing, advanced towards the river and attempted a flanking movement so as to cut Mardonius off from his base at thebes. The operation miscarried, and in their exposed condition the Greeks were severely harassed by the enemy's horse, which also blocked the Cithaeron passes against their supply columns. Pausanias thereupon ordered a night retreat to the hilly ground near Plataea, but the movement was badly executed; for whereas the Peloponnesians in the centre retired beyond their proper station, the Spartans and Athenians on the wings were still in the plain at daybreak. The Persians immediately fell upon these isolated contingents, but the Spartan infantry bore the brunt of the attack with admirable steadfastness, and both armies eventually renewed the struggle. The battle was decided by the Persians being overthrown and driven from the field. When this was stormed the enemy's resistance collapsed, and Mardonius's army was almost annihilated. This great victory was celebrated by annual sacrifices and a Festival of Liberation (Eleutheraia) in every fourth year at Plataea, whose territory moreover was declared inviolable.

In spite of this guarantee Plataea was attacked by Thebes at the beginning of the Peloponnesian War (431) and formally besieged by the Peloponnesians (429-37). The garrison after capitulating was put to death, and the city razed by the Thebans. The remaining Plataeans received a qualified franchise in Athens, and in 421 were settled on the territory of Scione. Expelled by Lysander in 404 they returned to Athens, until in 387 Sparta restored them in their native town, as a check upon Thebes. The city was again destroyed by Thebes in 373, and the inhabitants once more became citizens of Athens. Plataea was rebuilt by Philip and Alexander of Macedon, and during the rest of antiquity enjoyed a safe but obscure existence. It continued to flourish in Byzantine and Frankish times. The walls of the town, which at various periods occupied different portions of the triangular ledge on which it stood, remain partly visible. Recent excavations have discovered the Heraeum; but the temple of Athena the Warlike, built from the Persian spoils and adorned by the most famous artists, has not been identified.

PLATE. The word "plate" (connected with Gr. πλατής, flat, Late Lat. platea, and Span. plata, silver), in the sense to which it is reduced in the following article, is employed to denote works in silver or gold which belong to any class other than those of personal ornaments or coins. As implying a thin sheet of metal, the term has come to be used in various technical connexions, and has been transferred by analogy to other materials (e.g. glass). A "plate," as the common name for the table utensil (of whatever material), derives its usage partly from the metal prototype and partly from an etymological connexion with French plat, dish, Latin platus, flat. (See also Pewter; Sheffield Plate; Metal-Work.)

On account of the ease with which gold can be worked and the pure state in which it is generally found, it is probable that this was the first metal used by man; and it is certain that, in some countries at least, he attained to the most marvellous skill in its manipulation at a time when the other arts were in a very elementary condition. As an instance of this we may mention a sword of the bronze age, found in a barrow near Stonehenge, and placed in the museum at Devizes. The hill of this sword is covered with the most microscopically minute gold mosaic. A simple design is formed by fixing tesserae, or rather pins, of red and yellow gold into the wooden core of the handle. Incredibly as it may appear, there are more than two thousand of these gold tesserae to the square inch. The use of silver appears to belong to a rather later period, probably about 1500-1300 B.C. Though a widely spread metal in almost all parts of the world, it is usually found in a less pure state than gold, and requires some skill to smelt and refine it. Though both these precious metals were largely and skillfully used by prehistoric races, they were generally employed as personal ornaments or decorations for weapons. Except in Scandinavian countries, but little that can be called "plate" has been discovered in the early barrows of the prehistoric period in western Europe.

Ancient Egypt.—An enormous amount of the precious metals were carried to other parts of the world, and especially to the oriental kingdoms. According to Diodorus, who quotes the authority of Herodatus, the yearly produce of the royal gold and silver mines amounted to 32 millions of mines—that is, about 133 millions stedmig of modern money. Though this estimate is probably an exaggeration, the amount has probably been very great. The gold chiefly came from the Nubian mines in the western desert in the Wadi 'Alaki and the neighbouring valleys. A map of these mines, dating from the time of Ramses II. (1300 B.C.), has been preserved. Silver was not mined in Egypt itself, and came mostly from Asia Minor even at the earliest period. Then gold was comparatively common, silver a great rarity. Later, gold appears to have been relatively more abundant than silver, and the difference in value between them was very much less than it is now.

In the language of the hieroglyphs silver is called "white gold," and gold is the generic name for money—unlike most languages, in which silver usually has this special meaning—a fact which points strongly to the priority of the use of gold, which archaeological discoveries have rendered very probable. Among the treasures of the "royal tombs" at Abydos, dating to the 1st and 11th Dynasties, much gold was found, but no

---

1 In medieval English the term "plate" was occasionally used in the sense of a silver vessel. A curious survival of this use is still to be found at Oxford, where the servants may yet be heard asking at the buttery for so many "plates of beer," that is, silver tankards.

2 Hoare, Ancient Wilshire (1840).
silver. On the walls of one of the tombs at Beni Hassan there is an interesting representation of a gold- and silver-smith’s workshop, showing the various processes employed—weighing, melting, or soldering with the blow-pipe, refining the metal, and polishing the almost finished bowl or vase. Owing to the Egyptian practice of burying with their dead personal ornaments and jewelry, rather than other possessions less intimately connected with the person of the deceased, but few specimens of either gold or silver plate have survived to our times, whereas the amount of gold jewelry that has been discovered is very large, and shows the highest degree of skill in working the precious metals. We can, however, form some notion of what the larger works, such as plates and vases in gold and silver, were like from the frequent representations of them in mural sculpture and paintings. In many cases they were extremely elaborate and fanciful in shape, formed with the bodies or heads of griffins, horses, and other animals real or imaginary. Others are simple and graceful in outline, enriched with delicate surface ornament of leaves, wave and guilloche patterns, hieroglyphs, or sacred animals. Fig. 1 shows a gold vase of the time of Tethmosis (Thothmes) III. (Dynasty XVIII, about 1500 B.C.), taken from a wall-painting in one of the tombs at Thebes. The figure on its side is the hieroglyph for “gold.” Others appear to have been very large and massive, with human figures in silver or gold supporting a great bowl or crater of the same metal. Vases of this type were, of course, manufactured in Egypt itself, but many of those represented in the Theban tombs were tribute, mostly of Phoenician workmanship. Already as early as the time of Tethmosis III., when, as we know, the Phoenician cities had already existed for centuries, we find the ships of Arvad, of Byblos and of Tyre well known in the harbours of the Delta, and even bringing tribute of foreign vessels to the river quays of Thebes itself. We cannot doubt that much of the precious plate of gold and silver used by the Egyptians at this time and specifically described as foreign tribute was made in Egyptian or Egyptianizing style by Phoenician artists. But plate of really foreign type as well as origin was also brought to Egypt at this time by the Phoenician “Kefti” ships from Kefti, the island of Crete, where the “Minoan” culture of Cnosos and Phaestus was now at its apogee. Ambassadors from Kefti also brought gold and silver vases as presents for the Egyptian king, and on the walls of the tomb of Senmut, Queen Hatshepsut’s architect, at Thebes, we see a Keftian carrying a vase of gold and silver which is the duplicate of an actual vase discovered at Cnosos by Dr Arthur Evans. The art of the “Minoan” and “Myccenaean” goldsmiths exercised considerable influence upon that of the Egyptians; under the XXth Dynasty, about 1190 B.C., we find depicted on the tomb of Ramesses III., golden stirrup-vases (Brückkranz) of the well-known Myccenaean type, and in that of Imadua, an officer of Ramesses IX., golden vases imitating the ancient Cretan shape of the cups of Vaphio. In fact, it is more than probable that the Egyptians and Phoenicians manufactured plate of “Minoan” and “Myccenaean” types long after the ancient culture of Crete and the Aegean had come to an end. In the time of Ramesses III., about 1300 B.C., a clearly defined Asiatic influence appears in the decoration of some of the gold plate. A gold basket represented in the tomb of this king at Thebes, has on its side a relief of the sacred tree between two beasts, an Asiatic idea.

The chief existing specimens of Egyptian plate are five silver phialae (bowls), found at the ancient Thmuis in the Delta, and now in the Cairo Museum (Nos. 482-486 in the catalogue). These are modelled in the form of a lotus blossom, most graceful in design, but are apparently not earlier than the 4th century B.C. Of the splendid toretic art of a thousand years before, of which we gain an idea from the wall-paintings mentioned above, but few actual specimens have survived. The Louvre possesses a fine gold patera, 6½ in. across, with figures of fishes within a lotus border in repoussé work; an inscription on the rim shows it to have belonged to Thutti, an officer of Tethmosis III. (Mem. soc. ant. de France, xxiv. 1858). Thutti’s bowl is a typical specimen of the Egyptian plate of the XVIIIth Dynasty, and its design is precisely that of the hundreds of blue glazed faience bowls which were made at the time, and of which some perfect specimens and many fragments (especially from Deir el-Bahri) are in our museums. These were imitated from metal originals, just as most of the early Cretan pottery vessels were. A splendid bronze bowl, which shows us what some of the finer gold and silver plate was like, was found in the tomb of Hetaai, a dignitary of the XVIIIth Dynasty, at Thebes a few years ago, and is now in the Cairo Museum (No. 3553 in von Bissing’s catalogue). The engraved decoration, representing birds and animals in the papyrus-marshes, is very fine and evidently of native Egyptian work. The silver bowl at Berlin, said by de Closela to have come from Athienou in Cyprus, is certainly of XVIIIth Dynasty date, but, though purely Egyptian in style, more probably of Phoenician than Egyptian workmanship.

**Assyrian and Phoenician Plate.**—The art of making gold and silver plate, whether it originated in Egypt and passed thence to Crete or not, was evidently on its own ground in Egypt and in Minoan Crete. In Asia it was an exotic art, introduced from Egypt through the Phoenicians. In fact, it may be doubted whether any of the bronze imitations of plate found in Assyria are of Assyrian manufacture; they are probably Phoenician imports. The British Museum possesses a fine collection of these bowls, mostly found in the palace at Nimrud, and so dating from the 9th and 8th centuries (reigns of Assur-nazir-pal to Sargon). Though they are made of bronze, and only occasionally ornamented with a few silver studs, they are evidently the production of artists who were accustomed to work in the precious metals, some of them in fact being almost identical in form and design with the silver phialae found at Curium and elsewhere in Cyprus. They are ornamented in a very delicate and minute manner, partly by incised lines, and partly by the repoussé process, finally completed by chasing. Their designs consist of a central geometrical pattern, with one or more concentric

**Fig. 2.—Silver Bowl, about 7 in. in diameter, found in a tomb in Cyprus, with repoussé reliefs of Assyrian and Egyptian style.**
PLATE

Bulls, for instance, are usually represented as with a single mighty horn, curving to the front (in the style of the ancient Babylonian seals), rather than with both horns showing, in Egyptian fashion. When figures of men and women are shown, the principal groups are purely Assyrian imitations of Assyrian temple-reliefs, in fact—all as the sacred tree between the two attendant beasts, or the king engaged in combat and vanquishing a lion single-handed; while mingled with these are figures and groups purely Egyptian in style, such as the hawk-headed deity, or a king slaying a whole captive of captives at one blow. Occasionally one sees traces of the ancient Mycenaean influence, or perhaps rather of the young Ionian art which had now arisen out of the ashes of that of Mycenae. These Phoenician imitations are still good imitations. But a century or so later we meet with them again, this time on the silver bowls and dishes from Cyprus, in which the imitations have become bad. The same mixture of subjects was still in vogue, but confusion has been superadded to mixture, and we find kings in Assyrian robes and Egyptian wigs slaying Syrian dragons with Egyptian wings, and so on. Fig. 2 gives a silver dish from Curium containing examples of the above-mentioned subjects. It is a characteristic specimen of this mixed Phoenician art, of which di Cesnola seems to have collected a remarkable number of examples. In addition to the numerous silver phialae some were found with similar decoration, made of pure gold. To the same period belong the numerous silver bowls found in Assur and Cervetti in Italy. Those from the Regulini-Galassi tomb can hardly be earlier than the 6th century, so that this peculiar Mischkunst of the later type may well be dated to the 7th-5th centuries.

Prehistoric Greece: "Minoan" and "Mycenaean" Periods.—In the early history of the goldsmith's art no period is more important than that of the Greek Bronze age, the period of the prehistoric civilization which we call "Minoan" and "Mycenaean," which antedated the classical civilization of Greece by many centuries, and was in fact contemporary and probably coeval with the ancient culture of Egypt. In Greece during this, her first period of civilization, metal-work was extensively used, perhaps more extensively than it ever was in the history of later Greek art. So generally was metal used for vessels that even as early as the "Middle Minoan" period of Cretan art (some 2000 years B.C.) the pottery forms are obvious imitations of metal-work. The art of the metal-worker dominated and influenced that of the potter, a circumstance rarely noted in Egypt, where, in all probability, the decorative art was never so much patronized as in Minoan Greece, although beautiful specimens of plate were produced by Egyptian and Phoenician artists. Also but few of these have come down to us, and we are forced to rely upon pictured representations for much of our knowledge of them. It is otherwise in early Greece. We possess in our museums univalved treasures of ancient toretic art in the precious metals from Greece, which date from about 2500 to 1400 B.C., and as far as mass and weight of gold are concerned are rivalled only by the Scythian finds. These are the well-known results of the excavations of Schliemann at Troy and Mycenae and of others elsewhere. They do not by any means suffer in point of additional interest from the fact that they were made and used by the most ancient Greeks, the men of the Heroic age, probably before the Greek language was spoken in Greece.

The most ancient of these "treasures" is that discovered by Schliemann in 1873 buried, apparently in the remains of a box, deep in the fortification wall of Hisarluk the ancient Troy. It consists of vases and dishes of gold and silver, and of long tongue-shaped ingots of silver. In consonance with the early date (perhaps about 2500 B.C.) to which they are probably to be assigned (Schliemann ascribes them to the second Trojan city) these objects are all of simple type, some of the vases being unornamented jugs with tubular suspension-handles on the sides. Here we have metal imitating stonework, as, later, pottery imitates metal. These are of silver. A unique form in gold is a boat-shaped cup with handles at the sides (Plate I., fig. 23), at Berlin, which weighs 600 grammes. This is one of electrum (one part of silver to four of gold).

A feature of much the same date (the second "Early Minoan" period, about 2500 B.C. or before) was discovered in May 1908 in graves on the island of Mochlos, off the coast of Crete, by R. B. Seager. This is, however, of funerary character, like part of the treasures discovered in the shaft-graves of Mycenae, and, while including diadems, golden flowers, olive branches, chains, and so forth, for the adornment of the dead, does not include much gold used by the deceased during life.

The much later Mycenaean treasures include both funerary objects of thin gold and objects of plate that had actually been used. Among the former should be especially noted the bracelets, diadems and masks which were placed on the bodies of the chieftains whom Schliemann, great in faith as in works, honestly believed to be Agamemnon and his court (and he may not have been very far wrong). Among the latter we may mention the small flat objects of gold plate, little sphinkses and octopuses modelled in relief, small temples with doves, roundels with spiral designs, and so on, which were ornaments for clothing, and the golden plate decorations of weapon-handles. The greatest treasure, however, is the head with the gold rosette on its forehead of some object, probably helmeted, a beautiful object of price, and buried with its owner.

Similar protomes of bulls (of gold or silver) are brought by Minoan ambassadors as presents to the Egyptian court in the reign of Thothmes III. Gold and silver vases were found both in the shaft-graves, in the treasure-pit close by, and in chamber tombs at Mycenae. The most usual shape in the shaft-tombs is that well known to us from the vases of Vaphio, described below; among other types may be mentioned specially the &kappa;ιωσε ραμφετελησ with doves feeding above its handles (Plate I., fig. 21, from a restored reproduction) &νοικ &iota; πελεκες ἁμφις καστον χρυσον νεκρόνου; the golden jug with spiral decoration from the fourth grave; and the cup with lions of Egyptian appearance showing, as on the other round its bowl, found in grave 5. The fragment of a silver vase with a scene in high relief of slingers and bowmen defending their town against besiegers from grave 4 (Plate I., fig. 22), is an object unrivalled in ancient art. On this, as on the bull's head, we have gold overlaid on silver (with an intermediate plating of copper); on a silver cup from the same grave we find gold inlay, and on another silver cup, from a chamber-tomb, enamel and gold inlaid. How the Minoan goldsmith could combine silver with gold and the two with bronze we see on the marvellous inlaid dagger-blades from Mycenae, with their pictures in many-coloured metals of lion-hunts, cats chasing birds, and so forth, which show that he was perhaps the greatest master of all time in this art.

We speak of him as "Minoan," because most of the metal objects found at Mycenae are, if not of actual Minoan workmanship and imported from Crete, at any rate designed in accordance with the Minoan taste of the "Great Palace Period" (Late Minoan i. and ii.) at Cnosus. They are only "Mycenaean" in the sense that they were found at Mycenae. Of the art of the gold vase maker in the Mycenaean period properly speaking (Late Minoan iii.) we obtain an idea from the pictures of golden Bügelkanne with incised designs of zigzags, &c., represented on the walls of the tomb of Rameses III. at Egyptian Thebes. The objects from the Mycenaean shaft-graves are much older than this, as are also those from the next treasure we shall mention, that from Aegina, now in the British Museum. The gold cups and other objects of this treasure, with their fine but simple decoration, are certainly to be ascribed to the best Minoan period, although when first published Dr A. J. Evans was inclined to assign them to so late a date as c. a.d. 800. They are surely some seven hundred years older, having no characteristic of the decadent "sub-Mycenaean" period, as...
Dr. Evans would doubtless now agree. These objects were probably found in a tomb.

Dr. Evans's excavations at Cnossus, those of the Italians at Phaestos and Hagia Triada and those of the British school at Palaiakastro have not produced any very striking examples of the Minoan goldsmith's art in his own country, though splendid bronze bowls and vases have been found, which give us a good idea of what the plate must have been like, as do also the gilt statite imitations of plate mentioned below. One of the bronze vases from Cnossus exactly resembles one of gold and silver which was brought to Egypt by the ambassadors in Queen Hatshepsut's time (fresco in the tomb of Senmut). But we possess a fine silver cup (of the Middle Minoan period) from the American excavations at Gournia, and two examples of the finest Minoan gold plate, which were discovered outside Crete, in the famous "Vaphio cups," with their embossed representations of bull-netting, which have been illustrated so often as triumphs of ancient art (Plate L, figs. 24, 25). These are of Cretan workmanship, though found in Laconia, and are no doubt contemporary with the vessels of black statite with reliefs showing a harvest-home procession, gladiatorial combats, and a king receiving or bidding farewell to a warrior with his armed followers, which have been found by the Italians at Hagia Triada in Crete. These were originally overlaid with gold leaf, and are undoubtedly imitations in a cheap material of golden embossed vases of the same style as those found at Vaphio.

The period of the objects of gold and silver plate found by the expedition of the British Museum at Enkomi in Cyprus, which perhaps represent a somewhat later phase of Minoan art, but certainly cannot now any longer be regarded as belonging to the very late period to which they were at first assigned. One silver vase found at Enkomi is of the "Vaphio" type, which first appears in Cretan pottery as early as the Middle Minoan period, contemporary with the XIIth Egyptian Dynasty (c. 2000 B.C.), and even then is clearly an imitation of a metal original. Slightly modified, this type remained in use, as we find it represented among other golden vases on the walls of the tomb of Imislib or Imadu, an Egyptian official of the time of Rameses IX. (c. 1100 B.C.) at Thebes. But some, at least, of the Enkomi finds must be earlier than this.

The Egyptian representations of Minoan vessels of gold and silver in the tomb of Senmut at Thebes (c. 1500 B.C.) and of later Mycenaean golden Bügelkannen in that of Rameses III. (c. 1150 B.C.) have been mentioned already. During the age of Mycenaean and sub-Mycenaean decadence the art of the Greek goldsmith necessarily passed through a period of eclipse, to arise again, with the other arts, in rich and luxurious Ionian probably. The Homeric poems preserved for later days a traditional echo of the glorious works of the metal-workers of the Heroic age.

Etruscan Plate.—The Etruscans were specially renowned for their skill in working all the metals, and above all in their gold work. Large quantities of exquisite gold jewelry have been found in Etruscan graves and tombs, including, in addition to smaller objects, sceptres, wreaths of olive, and plates decorated with filigree-work and animal figures, which were used as personal ornaments (breastplates, girdles, diadems, &c.). In the Museo Kircheriano in Rome is a magnificent specimen of the last form of ornament; it is covered with nearly a hundred little statuettes of lions arranged in parallel rows; and the Vatican (Museo Gregoriano) possesses a very fine collection of similar objects from the "Regolini-Galassi" tomb at Caere. Little, however, that can be classed under the head of plate has yet been found.

Hellenic Plate.—The period of "geometrical" art which followed the Mycenaean age was one of decline in material prosperity and artistic skill. We possess some specimens of the work then produced in the precious metals in the gold diadems placed on the head of corpses interred at Athens (Archäologische Zeitung, 1884, pls. viii., ix.; cf. Athéniques Mittheilungen, 1896, p. 367; and G. Perrot and C. Chipiez, Histoire de l'art dans l'antiquité, vii. 245). The period of Oriental influence is represented by the finds of gold ornaments made at Camirus in Rhodes (see Greek Art, fig. 11). Fig. 3 shows a silver cup, with gold mounts, also found at Camirus, apparently a work of the same early date. A remarkable find of gold objects was made in 1882 at Vettersfeld in Brandenburg; the principal piece was a gold fish (see Greek Art, fig. 10) with ornaments in relief. These objects recall by their style early Ionic art, but were probably produced in one of the Black Sea colonies, since similar objects have been found, together with later work, in Crimian graves (see below), and exchanged for the amber of the Baltic coast. Cnossus especially encouraged the art, and paid enormous sums for silver vases and cups to the most renowned artists of his time, such as Glaukos and Theodoros the Samian.

The British Museum possesses a fine specimen of archaic Greek plate, found at Agrigentum in Sicily. This is a gold phial or bowl, about 5 in. across, with central boss or omphalos (φῶλας μοσχάριος) which seems once to have contained a large jewel. Round the inside of the bowl are six figures of oxen repousssé in relief, and at one side a crescent, formed by punched dots. A delicate twisted moulding surrounds the edge; the workmanship of the whole is very skilful (see fig. 4).

Pliny (N. H. xxxiii. 154 sqq.) gives a brief valuable account of the art of silver chasing (cadature, Gr. ṭροπητικ). In the best times of Greek art the chief works in gold and silver seem to have been dedicated to religious purposes, and to have been seldom used for the ostentation of private individuals. Vessels for the use of the temples, tripods in gold or silver

of the richest work, and statues of the gods were the chief objects on which the precious metals were lavished.  

The gold used by the Greeks probably came from Asia Minor or Egypt, while the mines of Laurium, in the mountains which form the promontory of Sunium in Attica, supplied an abundant amount of silver for many centuries. According to Pliny,

Pheidias was the first sculptor who produced works of great merit in the precious metals; he mentions a number of other Greek artists who were celebrated for this class of work, but does not give their dates. The chief of these were Mentor and Mys (both of the 5th century B.C.), Acragas, Boethus, the sculptors Myron and Stratonius, as well as the well-known Praxiteles and Scopas. In Pliny's time many works in gold and silver by these artists still existed in Rhodes and elsewhere. Among later workers he especially mentions Zopyrus, who made two silver cups, embossed with the scene of the judgment of Orestes by the Areopagite court, and Pytheas, who made a bowl with reliefs.

It is very probable that the Asiatic school of silversmiths had at least as much influence on Roman caelatura as that of Alexandria, whose importance has been overrated by Schreiber.

The finest extant examples of Greek plate are those found in the tumuli of south Russia, especially in the neighbourhood of Kertch, the ancient Panticapaeum. Fig. 5 shows a silver vase found in 1862 at Nikopol in the tomb of a native Scythian prince. The native horse-tamers of the steppes are represented on the shoulder with wonderful naturalism, and the work is beyond doubt that of an Athenian artist of the 4th century B.C. Splendid examples of goldwork were found in the tumulus of Kuloba, about 1/2 kilometres from Kertch, which was excavated in 1830 and found to be the burial-place of a Scythian prince and his wife. The jewelry and plate found in this tomb, which were clearly of Greek origin, comprised (amongst other objects) an electrum vase 15 cm. high, representing Scythians in their native costume, one of whom is extracting a neighbour's tooth, another binding up a wound, a third stringing a bow, besides several silver vases and two gold medallions with reproductions of the head of the Athena Parthenos of Pheidias. In these Crimean tombs are often found golden crowns in the form of oak leaves, some of which belong to late Roman times. The finest extant example of a gold wreath, however, is that discovered at Armento in south Italy and preserved in the Antiquarium at Munich; it bears an inscription of the 4th century B.C., showing that it was dedicated by a certain Kreithonios. In 1812 Dr Lee discovered at Ithaca a beautiful crater, 32 in. high (see fig. 6), and a phiale or patera, 0.5 in. across, both of silver, repoussé and chased, with very rich and graceful patterns of leaves and flowers picked out with gilding. These are probably not later than the 5th century B.C. Many silver mirror-cases, with repoussé figure-subjects in high relief, have been found at various places; as, for instance, one with a beautiful seated figure of Aphrodite found at Tarentum and now in the British Museum.

at Rome (Michaelis, *Das korinthische Silbergefäss*, 1859; cf. W. Amelung, in *Römische Mitteilungen*, 1906, pp. 289 sqq.) may reproduce the design of Zopyrus.

PLATE

The Victoria and Albert Museum contains an exquisite little silver vase, found in the ruins of Apollo at Vicarello in Italy (fig. 7), enriched with a band in low relief of storks devouring serpents executed with gem-like minuteness and finish—probably not later than the 3rd century B.C. The British Museum has a little vase of similar form and almost equal beauty, though perhaps later in date; it is decorated with bands of vine branches in a graceful flowing pattern, and is partly gilt.

**Greek-Roman Plate.—** During the last century of the Republic the growing luxury and ostentation of the wealthy Romans found expression in the collection of elaborate specimens of plate.

The works of the old Greek masters were the most highly prized, but contemporary artists, such as Pastel, also attained distinction in this branch of art. Amongst the numerous finds of silver plate made in modern times we may distinguish (a) temple treasures made of up of votive offerings, such as the treasure of Bernay in France (dep. Eure), discovered in 1830 and preserved in the Cabinet des Médailles, which belonged to the shrine of Mercurius Canetonnensis; (b) private collections, whose decoration recalls that of the Ara Pacis Augustae (see Roman Art), and a cylix with a seated figure of Athena in high relief, soldered on to the centre of the bowl, which appears to be of Greek workmanship. Such detachable figures were termed *emblemata*; in the Bosco Reale treasure is a cup with such a bust, typifying the province of Africa. Great value was also set upon *crustae*, i.e. bands of *repaussed* work forming an outer covering to a smooth silver cup (cf. the Rothschild vases, Roman Art). Such works commonly have Latin inscriptions incised on the foot giving the weight of the piece, the cup and *emblema* being weighed separately. The artistic value of Roman plate is discussed under Roman Art.

Among later specimens of Roman plate the most remarkable is the gold patera, nearly 10 in. in diameter, found at Rennes in 1777, and now in the Paris Bibliothèque—a work of the most marvellous delicacy and high finish—almost gem-like in its minuteness of detail. Though not earlier than about 210 A.D., a slight clumsiness in the proportion of its embossed figures is the only visible sign of decadence. The outer rim is set with sixteen fine gold coins—*aurei* of various members of the Antonine family from Hadrian to Geta. The central *emblema* or medallion represents the drinking contest between Bacchus and Hercules, and round this medallion is a band of *repaussed* figures showing the triumphal procession of Bacchus after winning the contest. He sits triumphant in his leopard-drawn car, while Hercules is led along, helplessly intoxicated, supported by bacchanals. A long line of nymphs, fauns and satyrs complete the circular band.

Late Roman plate is also represented by a series of large silver dishes, to which the same *missorium* is often, though perhaps wrongly, applied. These were used for presentations by emperors (whose portraits they sometimes bear) and distinguished officials. Three are preserved in the Cabinet des Médailles of the Bibliothèque Nationale at Paris—the "shield of Scipio," found in the Rhone near Avignon, about 26 in. in diameter, with a relief representing the restoration of Briesis to Achilles; the "shield of Hannibal," chiefly remarkable for its size (it is 72 cms. in diameter and weighs 10 kilogrammes); and a third, decorated with a group of Hercules and the Nemean lion. Other well-known examples of this form of art are the *shields* of Theodosius.

*Fig. 8.—Silver Crater, 153 in. high, from the Hildesheim find.* (Berlin Museum.)

The most famous of these are the Hildesheim treasure, in the Berlin Museum, discovered in 1869, which has been thought (without adequate reason) to have formed part of the campaigning equipment of a Roman military commander, and the Bosco Reale treasure, found in 1855 in a villa near Pompeii, whence its owner was endeavouring to remove it when buried by the eruption of Vesuvius. These collections contain pieces of various dates. The Bernay treasure, in part belonging to the 2nd century A.D., contains *oenochae* (ewers) with mythological subjects in relief inspired by classical Greek models—the theft of the Palladium was the subject of a famous cup of Pytheas, mentioned by Pliny—which must belong to the early imperial period. The Hildesheim treasure, again, contains two barbaric vases, without feet or handles, together with such fine pieces as the crater figured (fig. 8),

*Fig. 9.—Shield of Theodosius.*

and bottles were made (fig. 10). Those which still exist show a curious mingling of ancient Assyrian art with that of Rome in its decline. Reliefs representing winged lions, or the sacred tree between its attendant beasts, alternate with subjects from Roman mythology, such as the rape of Ganymede; but all are treated alike with much originality, and in a highly decorative manner. A fine example of Persian work of the early 15th century (dated 1417) is the circular gold dish, richly enamelled, which is in the Victoria and Albert Museum, though a large collection of Oriental plate may be studied. Here may be seen a gold rose-water sprinkler of gold, entirely covered with richly enamelled flowers, Mogul work, 17th century; fine Burmese gold work found in a.d. 1483-1485 in a Buddhist temple, Rangoon; remarkable gold ornaments of the Burmese regalia; and a large elephant howdah, from the Punjab, made of silver, parcel gilt, the top covered with silver plates of large repoussé foliage. Tibetan craftsmen work is represented by numerous vessels for sacred and domestic purposes, mostly of metal, partially mounted in silver, which display the skill of the Tibetans in the 14th century. Of the skill of the Hindus as goldsmiths, abundant evidence is afforded by the Ramayana and Mahābhārata, though very little of their ancient gold and silver work has survived. In India the people of the Cashmere valley have long been famous for their natural superiority as craftsmen, as was Lucknow for its utensils of gold and silver, much of it richly enamelled in the 18th and 19th centuries. Chanda in the Central Provinces was once celebrated for its skilled goldsmiths, and the plate of Cutch and Gujarāt in the Bombay Presidency has enjoyed a well-deserved reputation. The uncontaminated indigenous designs of the Sind goldsmiths' work call for special notice. Indian plate, as is quite natural, has often been influenced by European designs; for instance, the beautiful gold and silver work of Cutch is Dutch in origin, while the ornate throne of wood covered with plates of gold, early 19th century, used by Ranjit Singh (at South Kensington) also displays European influence. Much of the Siamese decorative plate of the 18th and 19th centuries is of silver-gilt and nielloed. In the Rijs museum, Amsterdam, is a collection of silver dishes, boxes of gold and silver, jewelry, &c., all of excellent workmanship, from Lombok. African goldsmiths' work is represented in the British Museum by the gold ornaments from Ashanti, where there are also some gold ornaments from graves in Central America and Colombia. Ancient Abyssinian work can be studied at the Victoria and Albert Museum in the gold chalice, gold crown of the Abuna of Abyssinia, another more ornate crown of silver-gilt, a fine shield with silver-gilt niello, and other objects.

The gold and silver work of Russia resembles in style that of Byzantium at an early period. Shrines and other magnificent pieces of plate in the treasury of the cathedral at Moscow (see Weltmann, Le Trésor de Moscou, 1861), though executed at the end of the 15th and 16th century, are similar in design to Byzantine work of the 11th or 12th century, and even since then but little change or development of style has taken place.

The caliphs of Bagdad, the sultans of Egypt, and other Moslem rulers were once famed for their rich stores of plate,
which was probably of extreme beauty both in design and workmanship. Little or nothing of this Moslem plate now remains, and it is only possible to judge of its style and magnificence from the fine works in brass and other less valuable metals which have survived to our time.

Towards the end of the 10th century the Rhine valley became the centre of a school of goldsmiths, who produced splendid examples of their work—a mixture of Byzantine art with their own original designs. The book-covers, portable altars and other objects, preserved at Trier and Aix-la-Chapelle, are notable examples produced at this centre. The magnificent book-cover from Echternach, now at Gothic, is of the school of Trier.

Early Medieval Plate.—The Gothic, Gaulish and other semi-barbarian peoples, who in the 6th century were masters of Spain, France and parts of central Europe, produced great quantities of work in the precious metals, especially gold, often of great magnificence of design and not without some skill in workmanship. The Merovingians encouraged the art of the goldsmith by spending immense sums of money on plate and jewelry, though only two examples of their great wealth in church vessels have survived—the gold chalice and paten of Gourdon, now at Paris. Fine examples of Carolingian work, which was mainly wrought in the monasteries in the north of the Frankish dominions and on the Rhine, may be studied in the covers for the Gospels, in the Bibliothèque Nationale in Paris. In 1537 a large number of pieces of very massive gold plate were found at Petrossa in Romania; much of this was unfortunately broken up and melted, but a considerable portion was saved, and is now in the museum at Bucharest. These magnificent objects are all of solid gold, and consist of large dishes, vases, ewers, baskets of open work, and personal ornaments (fig. 11). Some of them show a strong Roman influence in their design, others are more purely barbaric in style. To the first of these classes belongs a very fine phiale or patera, 10 in. in diameter. In the centre is a seated statuette of a goddess, holding a cup, while all round, in high relief, are standing figures of various male and female deities, purely Roman in style. Though the execution is somewhat clumsy, there is much reminiscence of classical grace in the attitudes and drapery of these figures. A large basket and other pieces, made of square bars of gold arranged so as to form an open pattern of stiff geometrical design, have nothing in common with the vessels in which Roman influence is apparent, and can hardly be the work of the same school of goldsmiths. The date of this Petrossa treasure is supposed to be the 6th century. The celebrated Gourdon gold cup and tray now preserved in Paris belong to about the same date. They are very rich and magnificent, quite free from any survival of classic influence, and in style resemble the Merovingian gold work which was found in the tomb of Childeric I. The cup is 3 in. high, shaped like a miniature two-handled chalice; its companion oblong tray or plate has a large cross in high relief in the centre. They are elaborately ornamented with inlaid work of turquoises and garnets, and delicate filigree patterns in gold, soldered on.

In the 6th century Byzantium was the chief centre for the production of large and magnificent works in the precious metals. The religious devotion and the great wealth of Justinian and his successors filled the churches of Byzantium, not only with enormous quantities of gold and silver chalices, shrines, and other smaller pieces of ecclesiastical plate, but even large altars, with tall pillared baldacchini over them, fonts, massive candelabra, statues, and high screens, all made of the precious metals. The wealth and artistic splendour with which St Peter's in Rome and St Sophia in Constantinople were enriched is now almost inconceivable.

To read the mere inventories of these treasures dazzles the imagination—such as that given in the Liber pontific rum of Anastasius Bibliothecarius, which includes the long list of treasures given by Constantine to St Peter's before he transferred his seat of empire to Byzantium (330), and the scarcely less wonderful list of gold and silver plate presented to the same basilica by Pope Symmachus (408-514). Some early Byzantine plate of the 6th century is in the British Museum; an inscribed paten of the 10th and 11th centuries is in Halberstadt Cathedral in Germany, and numerous ecclesiastical vessels are in the Treasury of St Mark's, Venice.

Early in the medieval period France and other Western countries were but little behind Italy and Byzantium in their production of massive works, both secular and religious, in the precious metals. At this time every cathedral or abbey church in Germany, France and even England began to accumulate rich treasures of every kind in gold and silver, enriched with jewels and enamel; but few specimens, however, still exist of the work of this early period. The most notable are Charlemagne's regalia and other treasures at Aix-la-Chapelle, a few preserved at St Peter's in Rome, and the remarkable set of ecclesiastical utensils which still exist in the cathedral of Monza near Milan—the gift of Queen Theodolinda in the early part of the 7th century. The treasure of Nagy-Szent-Miklos, consisting of several vessels of gold, of Hungarian origin (8th-9th century), is in the Imperial Museum at Vienna.

The existing examples of magnificent early work in the precious metals mostly belong to a somewhat later period. The chief are the gold and silver altar in Sant' Ambrogio at Milan, of the 9th century; the "Pala d'Oro," or gold retable, in St Mark's at Venice, begun in the 10th century; the silver altar-front in St Domenico's Church at Palermo; the shrine of silver-gilt (with later additions) in the church of St Simeon at Zara, Dalmatia, by Francesco di Antonio of Sesto near Milan, 1350; and the gold altar-frontal given by the emperor Henry II. and his wife Cunigunde, at the beginning of the 11th century, to the cathedral at Basel. The last is about 4 ft. high by 6 ft. long, repoussé in high relief, with figures of Christ, the three archangels, and St Benedict, standing under an arcade of round arches; it is now in the Musée Cluny in Paris. A similar gold frontal, of equal splendour, was that made for the archbishop of Sens in 999. This was melted down by Louis XV. in 1760, but fortunately a drawing of it was preserved, and is published by Du Sommerard (Album, 9th series, pl. xii.). Reliquaries of great splendour were made of the precious metals, one of the most notable being that containing the skulls of the three kings in Cologne Cathedral. This shrine, which resembles in form a building of two storeys, was wrought in the 12th century. The covers of the Textus in the Victoria and Albert Museum are highly important examples of goldsmiths' work; they are of gold and silver, decorated with enamel and set with stones, probably dating from the 12th century.

Celtic.—The skill in metal-working of the Celtic people in the British Islands, especially in Ireland, in Pagan and Christian times, is well known, and need hardly be emphasized here. While much has perished, much happily remains in proof of their extraordinary skill in working gold and silver, particularly in jewelry. The most remarkable specimen of their technical skill and artistic perception is the famous Ardagh chalice of the 9th-10th century (in the museum at Dublin) (Plate II., fig. 31), which is composed chiefly of silver, with enrichments of gold and gilt bronze, and with exquisite enamels. The interlaced ornament is a feature of Celtic work, and may further be studied in the celebrated Tara brooch and other similar pieces. The wealth of the Celts is perhaps best illustrated in the shields, belt-buckles, sword-hilts, and other objects, which are preserved in their burial-mounds. Celtic art is also seen in the numerous bronzes and other objects, found in the tombs of the Kentish barons, the Anglo-Saxons, and the Danes. These are of the most exquisite workmanship, and are full of interest as illustrating the art of the Celts, the early Saxons, and the Danes. Celtic art is also seen in the numerous bronzes and other objects, found in the tombs of the Kentish barons, the Anglo-Saxons, and the Danes. These are of the most exquisite workmanship, and are full of interest as illustrating the art of the Celts, the early Saxons, and the Danes.
ornaments. These are of great beauty, and the silver shrine of the bell of St Patrick (1091-1105) displays the interlaced scroll ornament in a striking degree. With the introduction of Gothic art into Britain the special characteristics of Christian Celtic art in Ireland gradually died out.

Anglo-Saxon.—Judged by the examples preserved in the Ashmolean Museum at Oxford, the Anglo-Saxon craftsmen brought their art to a high state of perfection, though hardly equal in merit to the Celtic. A large quantity of their metal-work is of bronze, frequently enriched with gold and enamel. Happily, there is preserved one priceless specimen of the goldsmith's art of this period—namely, the famous Alfred jewel of gold, now in the Ashmolean Museum at Oxford, with a portrait, believed to be of Alfred the Great, in cloisonné enamel. Another notable specimen is the Ethelwulf ring in the British Museum. Though ecclesiastical vessels, doubtless of the precious metals, appear in Anglo-Saxon illuminated manuscripts, the only piece of plate of that time at present known is the plain silver cup of the latter part of the 9th century, found with gold and silver jewellery and pennies at Trehiddle in Cornwall, which is now in the British Museum. There is, however, an important example of metal-work embossed with silver plates—namely, the portable altar of St Cuthbert at Durham.

A most valuable description of the various methods of work practised by gold- and silversmiths in the 11th and 12th centuries is given by the monk Theophillus in his Diversarum artium schedula (Hendrie's ed., 1847). He minutely describes every possible process. Silver could be employed in making and ornamenting elaborate pieces of ecclesiastical plate—such as smelting, refining, hammering, chasing and repoussé work, soldering, casting (by the "cire perdue" process), wire-drawing, gilding with mercury amalgam, and the application of niello, enamel and gems.

The silversmith of those days, as in classical times, was not only a thorough artist with a complete sense of beauty and fitness in his work, but he was also a craftsman of the most varied fertility of resource, and made himself thoroughly responsible for every part of his work and every stage through which it passed—a most striking contrast to the modern subdivision of labour, and eagerness to produce a show of neatness without regard to real excellence of work, which is the curse of all 19th-century handicrafts, and one of the main reasons why our modern productions are in the main neither works of true art nor objects of real lasting utility.

Italian Plate.—Before the latter part of the 15th century, large pieces of silver work were made more for ecclesiastical use than for the gratification of private luxury. The great silver shrine in Orvieto Cathedral, made to contain the blood-stained corporal of the famous Bolsena miracle, is one of the chief of these. It is a very large and elaborate work in solid silver, made to imitate the west front of a cathedral, and decorated in the most sumptuous way with figures cast and chased in low relief, and a wonderful series of miniature-like pictures embossed in low relief and covered with translucent enamels of various brilliant colours. This splendid piece of silver work was executed about 1338 by Ugolino da Siena, one of whose other works, a fine reliquary, is also at Orvieto. The other most valuable pieces of silver work in Italy are the frontal and retable of St James in the cathedral at Pistoia and the altar of San Giovanni at Florence. On these two works were employed a whole series of the chief Tuscan artists of the 14th and 15th centuries, many of whom, though of great reputation in other branches of art, such as painting, sculpture on a large scale, and architecture, did not disdain to devote their utmost skill and years of labour, to work which we now call a rule consign to craftsmen of the smallest capacity. The following celebrated artists were employed upon the altar at Florence: Antonio Pollaiuolo, Michelozzo, Verrocchio, as well as less prominent artisans, Betto Geri, Leonardo di Ser Giovanni and Betto di Francesco Betti.

Among the distinguished names of Florentines who during the space of one century only, the 15th, worked in gold and silver, the following may be given to suggest the high rank which this class of work took among the arts: Brunelleschi, Ghiberti, Donatello, Luca della Robbia, the two Pollaiuoli, Verrocchio, Michelozzo, Ghirlandaio, Botticelli, Lorenzo di Credi, Saccio Baldini and Francia. The cities of Italy which chiefly excelled in this religious and beautiful class of silver work during the 14th and 15th centuries were Florence, Siena, Arezzo, Pisa, Pistola, Bologna, where there are fine 14th-century silver reliquaries executed by Jacopo Rosceto da Bologna for the heads of St Dominic and St Petronio in the church of St Stefano, Perugia, where Paolo Vanni, Rosceto and others worked in the 14th and early 15th centuries, and Rome.

Owing to the demoralization and increase of luxury which grew in Italy with such startling rapidity during the early years of the 16th century, the wealth and artistic skill which in the previous centuries had been mainly devoted to religious objects were diverted into a different channel, and became for the most part absorbed in the production of magnificent pieces of plate—vases, ewers, dishes, and the like—of large size, and decorated in the most lavish way with the fanciful and over-luxuriant forms of ornament introduced by the already declining taste of the Renaissance. This demand created a new school of metal-workers, among whom Benvenuto Cellini (1500-1571) was perhaps the ablest and certainly the most prominent. His graphic autobiography makes him one of the foremost and most vivid figures of the wonderful 16th century, in which often the most basi]
among the most important pieces of plate. During the 16th century Augsburg and Nuremberg, long celebrated for their silver work, developed a school of craftsmen whose splendid productions have often been ascribed to the great Cellini himself. In the first decade of the 16th century, Paul Müllner, a Nuremberg goldsmith, furnished Frederick the Wise with several silver-gilt reliquaries for his collection at Wittenberg. Later in the same century came the Jamnitzer family of Nuremberg, chief among them being Wenzel Jamnitzer, one of whose masterpieces, an enamelled silver centre-piece, belongs to the baroness James de Rothschild of Paris. Mathaeus Wallbaum of Augsburg was another celebrated goldsmith of the 16th century. His chief works are religious ornaments of ebony mounted in silver, and the Pommerischer Kunstschrank in the Kunstgewerbe Museum, Berlin. But the chief German goldsmith of the 16th century was Anton Eisenhoit of Warburg, who wrote the fine crucifix (1560), the chalice and other ecclesiastical vessels which belong to the Fürstenberg family. Other notable craftsmen of this period were Hans Petzolt and Melchior Bayr, the latter having made the silver altar (with scenes from the Life of Christ after Dürer) of the 13th century; the cup given by the emperor Frederick III. and Mathias Corvinus to Vienna in 1462, and the splendid ewer of Goslar, 1477, are notable specimens of early German work. In England the only public collection of German plate worthy of notice are the Waddesdon Museum, and the Victoria and Albert Museum. Prior to its dispersal among his five daughters, the late baron Carl von Rothschild's collection at Frankfurt-on-Main was the most extensive private collection in existence. The Guttmann collection, acquired by Mr. J. Pierpont Morgan, contains many rare pieces, as does that of the baronesses Alphonse and Salomon de Rothschild in Paris.

Many of the most beautiful vessels of crystal, agate, &c., formerly attributed to Italian artists, were carved and engraved and set in beautiful enamelled gold and silver mounts, in southern Germany in the 16th and 17th centuries. At the end of the 17th and the beginning of the 18th centuries household plate and other ornaments were frequently decorated with painted enamels, mostly originating from Augsburg. Dinglinger of Dresden and his school at about this time exercised considerable influence in the production of ornaments in pearl and other materials, elaborately carved, mounted and enamelled.

Several specimens exist of the models of cups required of candidates for the rank of master-craftsmen in the second half of the 16th century. One of these, at the Victoria and Albert Museum, is believed to have been wrought by Martin Rehlein of Nuremberg in 1572-1573. Many of the famous 15th and 16th century artists—such as Martin Schön, Israel von Mecken, Adergrewer, Altdorfer, Brosamer, Peter Flötner, the Behams, Hopfer and Hans Holbein the younger, supplied the silversmiths with designs for plate. Several of Holbein's original designs, including one for the gold cup probably wrought by his friend, John of Antwerp, for Queen Jane Seymour, are in the Print Room, British Museum, where there is also an original design for a table fountain by the celebrated artist, Albrecht Dürer. Virgil Solis of Nuremberg (1514-1562) was especially fertile in designing plate, and he executed a large series of etchings of designs for vases, cups, ewers, tazze, &c. Many of the German silver ewers and basins resemble those made in pewter at the end of the 16th century by François Briot and Gaspar Enderlein, who migrated from Switzerland to Germany.

Switzerland.—This country produced several silversmiths whose work in the main follows that of the German school. The three historical beakers in the national library at Zurich were made in that city from money sent out as gifts from England by the three English bishops, Jewel of Salisbury, Horn of Winchester, and Parkhurst of Norwich, in appreciation of the hospitality afforded them during their exile at Zürich, in the reign of Queen Mary I. Important plate was wrought at Berne, Rapperswill and other Swiss towns.

Russia.—In no country is the ecclesiastical and secular plate of greater interest than in Russia, where so many different influences have been at work in its designs and decoration—Byzantine, Oriental, Gothic, Renaissance, &c. The "golden age" of ecclesiastical art was undoubtedly the 17th century, when the churches and monasteries were being enriched with many priceless ornaments in the precious metals. Enamels of great richness—which had been introduced there by Hungarian artists—niello and precious stones were employed in the decoration. A drinking-cup or bowl exclusively Russian in form and character, known as braïna, was largely made (see the fine one of gold, enamelled and set with precious stones, in the royal collection at Vienna), as was a smaller bowl, called oara, with a single handle. Another secular vessel, peculiarly Russian, is the konsh, a pointed or boat-shaped bowl with a long handle. Much of the domestic plate after Peter the Great's time was influenced by that of western countries, particularly Germany.

Poland.—Though not without a character of its own, the German influence was never so marked as that of Russia.  

Lessing, Die Silber-Arbeiten von Anton Eisenhoit (1880).

Fig. 13.—Silver Cup, 8½ in. high, usually attributed to Jamnitzer, but more probably by Paul Flint. Made at Nuremberg about the middle of the 16th century. (S. K. M.)

Fig. 14.—Ewer by François Briot, about 10 in. high. Middle of 16th century.
eclesiastical plate of Poland came under the influence both of Germany and Hungary. Many of the sacred vessels of late medieval times are decorated with enamels and niello. In the 17th century ecclesiastical vessels encrusted with corals are met with, such as those given by Michael Wisiowski, king of Poland, to the church of Czestochowa. A magnificent 17th-century chalice of gold, beautifully enamelled, given by the bishop of Plock and Breslaw, son of Sigismund III., is in Plock cathedral. Many important pieces of plate still exist in churches in Poland, though a Polish origin is not claimed for them; for instance, the 16th-century chalice at Trzemesno, where there is also another chalice of about the same period. The cathedral of Cracow contains many priceless examples, such as the 14th-century gold cross given by Casimir the Great; the gold crucifix of Mathias Corvinus, and the gold reliquary, 16th century, of St Stanislas, bishop of Cracow.

France.—France, like England, has suffered grievous losses in its plate, though it can show a larger array of medieval church vessels than can England. The chief specimens of medieval plate are the 9th-century casket and the seated statuette of St Foy (10th century) in the treasury of Conques; the cross of Leon (c. 1200) in the Louvre; the chiseler (early 13th century) in the treasury of Sens; the cross of the same period in Amiens Cathedral; the caskets of St Taurin (c. 1250); the reliquary of St Epine, given by St Louis, the virgin abbey of Roncevaux (Navarre, 14th century); and the virgin given by Queen Jeanne d’Evreux to St Denis in 1339. One of the most cherished possessions of the British Museum is the celebrated gold and enamel cup of the kings of England, French work of the 14th century. No doubt the visit to Paris of Cellini exercised a great influence in the goldsmith’s art there, though, unfortunately, no examples have survived. The extravagances of Louis XIV. and his court led to the destruction of all the royal plate of France, as did the Revolution of 1789 of vast quantities of domestic plate. It was not until the early part of the 18th century that any signs of revival are visible in part of the silversmiths. Chief among the Paris goldsmiths of that time are Claude Ballin the younger, Thomas Germain, and, later in the century, Francois Thomas Germain, who made the royal plate of Portugal and several pieces for the court of Russia.

The Low Countries.—Flemish silversmiths of the late medieval period were as skilful as they were in the Renaissance. So little Flemish plate remains that pictures of the Flemish school are recommended as the chief sources of study of ecclesiastical vessels. A fine covered silver beaker, decorated with open work and translucent enamel in the South Kensington Museum, and another covered with figures and foliage in niello, in the print room of the British Museum, are considerable examples of Flemish work of the 15th century. A large triptych, 13th century, is in the Rothschild bequest to the Louvre. Ornate rosewater ewers and basins, which came in with the Renaissance, such as the important pair dated 1355 in the Louvre, were made at Antwerp and other places.

The Utrecht silversmith, Paul van Vianen (early 17th century) wrought many fine pieces of plate, including the silver bas-reliefs in the Rijks Museum at Amsterdam, where there are five fine bas-reliefs in silver by the Belgian silversmith, Mathias Melin. Two other members of the same family, Adam and Christian van Vianen, were also prominent silversmiths of this time. An earlier Dutch silversmith, Christian van Vianen of Utrecht, made the vessels for the altar of St George’s Chapel, Windsor, for Henry VIII.

Two important pieces of Dutch plate are the covered tazzashaped cup of William the Silent, date about 1573, belonging to the earl of Yarborough, 1 and another large cup of the same form (1595), known as the "Breda cup," in the possession of the Hohenlohe family. Considerable quantities of plate were produced at Amsterdam (where Johann Lutma the elder—d. 1660—was a well-known silversmith), Haarlem, the Hague and many other places. The numerous 17th-century Dutch pictures

Spain and Portugal.—Spanish plate was largely influenced in the middle ages by that of France and Flanders and the art of the Moors. But little medieval plate exists in Spain, most of it having been destroyed at the time when a taste for more elaborate ornaments sprang up as a result of the introduction of fresh wealth from the colonies in the New World. The following examples may be singled out: a cross of wood, covered with gold filigree work, set with stones (A.D. 868), in Oviedo Cathedral, where there is also a larger cross of wood and gold, dating from later in the same century. A Moorish casket of wood covered with thin silver plates, in Gerona Cathedral. The reliquary of Alphonso III. and his queen (A.D. 866-868 covered with embossed silver plates of the symbols of the evangelists; the 11th-century chalice at Silos; chalices of the 13th and early 14th centuries in the cathedrals of Santiago and Toledo; and Don Martin’s great armchair, of wood covered with elaborate silver-gilt plates, in Barcelona cathedral. The Spanish monsternances of the 15th century are noticeable because of the Flemish influence displayed, while those of the early part of the 16th century, such as that by the celebrated silversmith, Enrique de Vaca, in the cathedral of Cordova, is remarkable for its ornate character. The latter’s grandson, Juan de Arfe y Villafane (who wrote De varia commensuracion, 1586, on silverwork and other arts) became a chief maker of these magnificent monstrances; for instance, the celebrated example in Seville cathedral. He was associated with Pacheco in executing statues. About the 15th century Barcelona became famed as a centre for the silversmith’s art, and the Libros de pasantia, or silversmiths’ examination books, still preserved in that city, contain a large number of designs for jewel-work. Seville likewise had an important gild of silversmiths, as did the following cities: Toledo, Valladolid, Burgos, Cordova and Salamanca. The celebrated family of Becerreia wrought fine plate at Cuerna in the 18th century. Many chalices and some domestic plate of the 16th and early 17th centuries are embossed with small enamelled disks, some of which show Saracenic influence in details. The Victoria and Albert Museum possesses a fine collection of Spanish goldsmith’s work.

Portuguese plate displays in its Gothic features a very florid style, in imitation of that adopted by architects in the reign of Don Manuel (1495-1521). A typical example of this extravagance of Gothic motives may be seen in the monsternance of Belem, which was made from gold brought from the East by Vasco da Gama.

Austria and Hungary.—Austrian plate is, like that of Switzerland, largely based on German models. The ecclesiastical plate of Hungary in the 15th and 16th centuries is celebrated for its enamelled work of a flowered design enclosed in filigree wire—introduced from Italy. This enamelled decoration was continued in the 17th century, but without the filigree wire, and it is then described as “Transylvanian.” Much of the secular plate in the 16th and 17th centuries in north and east Hungary is influenced by German plate, while that in Transylvania is frequently inspired by Oriental designs.

English.—There is little Correton of the importance attached to English medieval plate by Continental peoples, as there was to the magnificent English illuminated MSS., and, later, to the embroidered vestments, opus Anglicanum. But, unfortunately, the ruthless destruction of plate by the Wars of the Roses, the Reformation and the Great Rebellion has spared but few medieval pieces to which we can point. Under the name of Protestantism every ecclesiastical vessel with a device savouring of “popish superstition” was instantly destroyed. The inventories of the great cathedrals and religious houses plainly reveal their marvellous wealth in gold and silver vessels.

Norfolk is richer than any other county in pre-Reformation chalices and patens. The well-known “Gloucester” candlestick, "Norfolk Arch. xii. 85."
PLATE

though composed of inferior metal, is an illustration of the fine plate wrought in England in the 12th century, while the ancient anointing spoon of the sovereigns of England at the Tower of London is an historical relic of the end of the 12th century (with the bowl altered for Charles II.). The earl of Carysfort is the fortunate possessor of a silver-gilt censer of about 1375 and an incense ship, of about 1400, found in Whitlesea Mere in 1850, and formerly belonging to Ramsey Abbey. Only one pre-Reformation English gold chalice has survived, with its paten and a silver crozier was given to Corpus Christi College, Oxford, by its founder, Bishop Foxe (Plate II., fig. 26). Both bear the London date-letter for 1507-1509. Another historical relic which has come down to the present day, though in a restored form, is the gold amphora of about the end of the 14th century in the Tower of London. The universities of Oxford and Cambridge, though sadly depleted of their plate, can still show some notable pieces. The earliest example at each is a drinking horn, both of the 14th century, at Queen's College, Oxford, and Corpus Christi College, Cambridge. Other notable horns are the Pusey horn; the celebrated Bruce horn, with the seals of John of Gaunt attached, and one at Christ's Hospital.

Mazer bowls, made of wood mounted in silver and even in gold, and frequently engraved with scriptural and other inscriptions (see Plate II., fig. 28), were popular drinking vessels in England in medieval times. Many of these have survived, the earliest specimen being one of Edward II. at Harbledown hospital. They ceased to be made after the reign of Elizabeth (Archeologia, i. 120). Medieval coco-nut cups, mounted in silver, are of frequent occurrence in England, the best known examples being in the possession of the colleges at Oxford and Cambridge and several of the city companies. As has been mentioned before, but few examples of early plate exist; the following is a brief list of some of the most notable pieces, other than those previously enumerated: the "Solkorn" cup (c. 1450), and the "Anathema" cup (1481-1482) at Pembroke College, Cambridge; the Leigh cup (1499) at Mercers' Hall; the ivory and silver cup (1525-1526) of the duke of Norfolk; the pastoral staff (c. 1567) at New College, Oxford; the Richmond cup (c. 1510) at Armourers' Hall; the "election cup" (c. 1520) at Winchester College; and the Foundress' plate, consisting of a fine covered cup (1435-1440), two salts (c. 1500), a beaker and cover (1507-1508), and a salt (1507-1508) at Christ's College, Cambridge. Of Elizabeth's reign, the finest examples are probably the salt of the Vintners' Company (Plate II., fig. 27), and the rosewater dish and ewer of the duke of Rutland. Stoneware jugs, as the well-known example (1581) from West Malling, Kent, and Chinese porcelain vessels were elaborately mounted in Elizabethan times, a goodly proportion of the former having been done by goldsmiths at Exeter.

The Celtic races of both England and Ireland appear to have possessed great wealth in gold and silver, but especially the former. It seems, however, to have been mostly used in the manufacture of personal ornaments, such as torques, fibulæ and the like. A magnificent suit of gold armour, repoussé with simple patterns of lines and dots, was found some years ago at Mold in Flintshire, and is now in the British Museum. The amount of old jewellery found in Ireland during the past century has been enormous; but, owing to the unfortunate law of "treasure-trove," by far the greater part was immediately melted down by the finders. Little of this period that can be called plate has been discovered in the British Isles—unlike Denmark and other Scandinavian countries, where the excavation of tombs has in many cases yielded rich results in the way of massive cups, bowls, ladles and horns of solid gold, mostly decorated with simple designs of spirals, concentric circles, or interlaced grotesques. Others are of silver, parcel-gilt, and some have figure subjects in low relief (fig. 15). In like manner, during the Saxon period, though gold and silver jewelry was common, yet little plate appears to have been made, with the exception of shrines, altar-frontals and vessels for ecclesiastical use, of which every important church in England must have possessed a magnificent stock. With regard to English secular plate, though but few early examples still exist, we know from various records, such as wills and inventories, that the 14th century was one in which every rich lord or burgier prided himself on his fine and massive collection of silver vessels; on festive occasions this was displayed, not only on the dinner-table, but also on sideboards, arranged with tiers of steps, one above the other, so as to show off to advantage the weighty silver vases, flagons and dishes with which it was loaded. The central object on every rich man's table was the "net"—a large silver casket, usually (as the name suggests) in the form of a ship, and arranged to contain the host's napkin, goblet, spoon and knife, with an assortment of spices and salt. No old English "nefs" are now known. Great sums were often spent on this large and elaborate piece of plate, e.g. one made for the duke of Anjou in the 14th century weighed 348 marks of gold. The English silversmiths of this period were highly skilled in their art, and produced objects of great beauty both in design and workmanship. Of the finest specimens of Edward III.'s plate which still exists is a silver cup belonging to the mayor and corporation of King's Lynn. It is graceful and chalice-like in form, skilfully chased, and decorated in a very rich and elaborate way with coloured translucent enamels (fig. 16) of ladies and youths, several with hawks on their wrists. Silver salt-cellers were among the most elaborate pieces of plate produced during the 15th century. Several colleges at Oxford and Cambridge still possess fine specimens of these (fig. 17); a favourite shape was a kind of hour-glass form richly ornamented, made between about 1480 and 1525.

2 Archaeologia, iii. 3, sili. 377.
3 Ibid. xxvi. 422.
But few existing specimens of English plate are older than the beginning of the 15th century. Among the few that remain the principal are chalices—such as the two large silver-gilt ones found in the coffin of an archbishop of York, now used for holy communion in the cathedral, and a fine silver chalice from the church of Berwick St James, Wilts, now in the British Museum. Both this and the York chalices are devoid of ornament, and, judging from their shape, appear to be of the first half of the 15th century, which is the date of the fine medieval chalice and paten found near Dolgelly some years ago (the latter now believed in some quarters to be of German origin). Several Tudor cups are in existence: the celebrated one of 1521 (Plate II., fig. 30), an earlier one, 1500; two covered ones of about 1510 and for Sandwich and Wymeswold, respectively; one (1532) at Corpus Christi College, Oxford, and the Bodkin cup (1532) of the Corporation of Portsmouth. A very early beaker (1496) is in a private collection, as is also a small Tudor bowl (1525-1536).

The earliest known chalices of silver include the Gourdon chalice and paten, the St Gozlin chalice at Nancy (10th century); the 12th-century specimen in the abbey of Wiltten in Tirol.

It is interesting to note the various changes of form through which the ecclesiastical chalice passed from early Christian times till the 16th century. It was at first an ordinary secular cup with two handles, classical in form and of large capacity, because the lityra as well as the chalice received the wine. The double handles were of practical value in passing the cup round like a modern "loving cup." The first alteration was the omission of the handles, so that it took the form of a large hemispherical bowl, with a round foot, and a knob for security in holding it. For some centuries it appears to have been the custom for the priest to hold the chalice, while the communicant sucked the wine through a silver tube or "fistula." Some of the most magnificent early examples of this form of chalice have the bowl mounted in hands, set with jewels, and enriched with minute filigree work—a design which appears to have been taken from those cups, such as the four magnificent examples in the treasury of St Mark's at Venice, which have their bowl cut out of crystal, onyx or some other precious stone. The finest of this class are the Ardagh chalice, now in the Dublin Museum, and the chalice of St Remigius, in Reims cathedral; both are most magnificent specimens of the taste and skill of 10th to 11th century goldsmiths. In the 12th and 13th centuries the design becomes simpler; there is a distinct shaft, extending above and below the knob; and on the foot is marked a cross, not found in the earlier ones, to show which side the priest is to hold towards himself at celebration. The next alteration in the form of chalice, which occurred in the 14th century, was to make the foot not circular in plan but polygonal or lobed, so that the cup might not roll when laid on its sideward, after it had been rinsed out. This form lasted in most countries till about 1500, and in England till the Reformation. Then the bowl, which in the previous two or three centuries had been slowly reduced in size, owing to the gradually introduced practice of refusing the wine to the laity, was suddenly made more capacious, and the form was altered to the shape shown in fig. 18, in order that the Protestant "communion cup" might bear no resemblance to the old Catholic "massing chalice." This was ordered to be done in 1562 (see Arch. Journal, vol. 33, p. 169). The best account of the evolution in the form of English medieval chalices and patens is by W. H. St John Hope and T. M. Fallow, in Archaeologia, vol. xliii.

Secular plate during the 15th and 16th centuries was frequently similar in style to that made in Germany, though the English silversmiths of the latter century never quite equalled the skill or artistic talent of the great Nuremberg and Augsburg silver-workers. In the 17th century, during the reigns of James I. and Charles I., many fine pieces of plate, especially tall cups and tankards, were made of very graceful form and elegance. In the 18th century all ecclesiastical, especially the fine collections belonging to the universities, were melted down during the Civil War. In Charles II.'s reign returning prosperity and the increase of luxury in England caused the production of many magnificent pieces of plate, often on a large scale, such as toilet services, wine-coolers, and even fire-dogs and other furniture. These are very florid in their ornament, much of it under Dutch influence, and mostly have lost the beautiful forms of the century before (fig. 19 and Plate II., fig. 29). In the early part of the 18th century the designs of English plate were to some extent influenced by the introduction of French ornaments by the large band of French silversmiths who sought refuge in England after the revocation of the edict of Nantes. Chief among these Frenchmen (though probably not a refugee himself) was Paul Lamerie, who produced a large number of notable specimens, the largest of which is a fine wine-cooler in the Winter Palace, St Petersburg. Through the greater part of the reign of George III. English plate is more remarkable for its plain solidity than for artistic merit. With the advent, however, of the talented architects, the brothers Adam, came a taste for plate with classical characteristics. The South Kensington Museum has a small, though fine, collection of plate, varying in date from 1770 to 1788, in the Adam style. Many of Flaxman's designs were produced in plate; among the most important being the "Shield of Achilles," in silver-gilt, at Windsor Castle. Thomas Stothard, the painter, executed several designs for goldsmith's work for Rundell and Bridge.

The Assay of Gold and Silver Plate. The primitive method of testing the purity of the metal was by marking a streak with it on the touchstone, and comparing the colour of the mark with that made by various pieces of gold or silver of known degrees of purity. Assay by cupellation is now employed for silver: a piece of the silver to be tested is melted with some lead in a cupel or bone-ash crucible; the lead is oxidized, and rapidly sinks into the bone-ash, carrying with it any other impurities which are present. The residue of pure silver is then weighed, and by its loss shows how much alloy it contained. Gold is now tested by an elaborate chemical process by which the trial bit is dissolved in acid, and then thrown down in the form of precipitate, which can be examined by a careful quantitative analysis (see ASSAYING).

The standard of purity required in the time of Edward I. was, for gold, that it should be of the "Paris touch," i.e. 191 carats out of 24. Before then 22 carats was the standard. Silver was to be "of the sterling alloy," viz. 11 oz. 2 dwt. to the pound. Except for a time during the 16th century this standard of silver has been kept up, and is still required by law.

Hall-marks on Silver. In the 13th century the English Gild of Gold-and-Silver-smiths had grown into great importance, and had acquired monopolies and many special privileges. In order to keep the standard up to the required purity the system of requiring each article to be stamped with certain marks was introduced by royal command. The first of these was the

---
king’s mark—a leopard’s or lion’s head crowned. This was introduced in 1306 by Edward I. (26 Edw. I. stat. 3, c. 30). The second, the maker’s mark, was instituted in 1363 (37 Edw. III. c. 7). This might be any badge or initial chosen by the master silversmith himself. The third was the Year letter or assayer’s mark; this was an alphabet, one letter being used for a year, counting from the day of the annual election of the warden of the Goldsmiths’ Company. When one alphabet was exhausted another with differently shaped letters was taken. The earliest existing piece of plate bears this mark. It has the three marks in reverse (with paten, 1479–1480), at Nettlecombe, Somerset. Other marks, subsequently introduced, were the lion passant, first used in 1544; the lion’s head erased; and a full-length figure of Britannia, used only between 1679 and 1719–1720; and, lastly, the portrait of the reigning sovereign, which was used from 1784 to 1890, when the duty on gold and silver plate ceased. In addition to these general hall-marks, the plate made in various provincial towns had certain special assay and hall-marks.

The best work on hall-marked plate and the marks themselves, with the history of the Goldsmiths’ Company, is C. J. Jackson’s English Hall-Marks and their Marks (1895), where will be found illustrations of the marks found on plate wrought in Scotland and Ireland, and at English provincial gilds—York, Norwich, Exeter, Chester, Lincoln, Newcastle, Birmingham, Sheffield and other places. Also illustrations of the English Gold Plate (1907) illustrates and describes gold plate only.

Modern Plate in the East.—Though little plate of real artistic merit is now made in Europe, in the East among the Moslem and Hindu races there still survive some real taste in design and skill in execution. Delhi, Benares, Lucknow, Cutch and other places in India and Kashmir still produce a quantity of beautiful silver and gold work—chiefly ewers, basins, rose-water sprinklers, salvers, coffee-pots and the like. These are of graceful form, covered with rich repoussé work, or more often with very delicate chased patterns. Their style in the main is Moslem, but some combine an Arab form with native Indian surface decoration. This class of work is not a revival, but has been preserved and handed down by unbroken tradition, and with little or no change in style from the 16th century or even earlier.1 The silversmiths of Persia, Damascus and other Eastern places are still skilful, and retain some old tradition in their designs. They are, however, more occupied in the production of personal ornaments than in making larger works of silver or gold.

PLATEAU, JOSEPH ANTOINE FERDINAND (1801–1883), Belgian physicist, was born at Brussels on the 14th of October 1801, and died on the 15th of September 1883 at Ghent, where he had been professor of physics from 1835. He was a pupil and friend of L. A. J. Quetelet, who had much influence on the early part of his career. The more original investigations of Plateau refer chiefly to portions of one or other of two branches of science—physiological optics and molecular forces. We owe to him the "stroboscopic" method of studying the motion of a vibrating body, by looking at it through equidistant radial slits in a revolving disk. In 1839 he imprudently gazed at the midday sun for 20 seconds, with the view of studying the after effects. The result was blindness for some days, succeeded by a temporary recovery; but for the next fourteen years his sight gradually deteriorated, and in 1843 he became permanently blind. This calamity did not interrupt his scientific activity. Aided by his wife and son, and afterwards by his son-in-law G. L. van der Mensbrugge, he continued to the end of his life his researches on vision—directing the course of the experiments which they made for him, and interpreting the bearing of the results. He also published a valuable analytical catalogue of all the more important memoirs which had been written, from the earliest times to the end of the 18th century, on his favourite theme of subjective visual phenomena. But even more extra- ordinary results were obtained from the experimental study of electrical forces, embracing hundreds of novel experiments whose results he saw only with others' eyes. These form the subject of his great work Statique expérimentale et théorique des liquides soumis aux seules forces moléculaires (2 vols., 1873), a valuable contribution to our knowledge of capillary phenomena. His son, Félix Auguste Joseph Plateau (b. 1841), became professor of zoology and comparative anatomy at Ghent in 1870.

PLATEAU (a French term, older platel, for a flat piece of wood, metal, &c., from plat, flat), in physical geography, an elevated region of level or gently undulating land-surface, the term being synonymous with "table-land." The most clearly defined platelans in contrast with Oriental steppe-plateaux have steep flanks calculated to hark back to the glacial period, but the term does not necessarily connotes a steep ascent from the surrounding country. Indeed, it is applied to such diverse forms as the high-lying plains encircled by the higher elevations of the Andes, and to those of the west of North America, which rise almost imperceptibly from the low central plains. A plateau may have its origin either in the upheaval of strata which preserve their original horizontal position during the process, or in the prolonged denudation of an originally broken surface. The two forms are distinguished respectively as Plateaus of Deposition and Plateaus of Erosion.

PLATED WARE, articles chiefly intended for table use consisting of an inferior metal or alloy covered by one of the precious metals, with the object of giving them the appearance of gold or silver. Before the introduction of electro-plating (the invention of which in 1742 is associated with the name of Thomas Boulsover, of Sheffield) was to fuse or burn together, by a flux of borax, a thin sheet of silver on each side of an ingot of base metal, generally copper, or German silver, which is an alloy of copper. The silver plates were firmly wired to the ingot, which was then placed in a heated furnace and brought nearly to the fusing-point of the silver. The artisan knew the exact moment to withdraw the ingot. When cold it was rolled down, a sheet, and from such sheets "silver-plated" articles were made. Articles like dish-covers were originally only silver-plated on one side, and after being worked into shape were tinned inside with pure tin. In Birmingham bar-copper was the base metal used; when bare of silver this showed blood-red. The Sheffield manufacturers, on the other hand, used shot-copper mixed with brass (an alloy of copper and zinc) in the proportion of 4 or 6 to 1. In this way they got rid of the redness of the copper and rendered it harder, and their product is the "old Sheffield plate" (q.v.) that has become famous all over the world. This method of plating rapidly declined with the introduction of the newer process of electro-plating (q.v.), by which it has been superseded. Plating with nickel is extensively used for bedsteads and other articles of upholstery, and for various parts of bicycles, steamships, railway carriages, &c. Steel sheets are also plated with nickel for cooking purposes, and iron is plated with brass.

PLATEN-HALLERMUND, AUGUST, GRAF VON (1760–1835), German poet and dramatist, was born on the 24th of October 1760 at Ansbach, the son of the Oberforstmeister in the little principality of that name. The latter, together with otherFranconian principalities, having shortly after his birth become incorporated with Bavaria, he entered the school of cadets (Kadettenhaus) in Munich, where he showed early promise of poetical talent. In 1810 he passed into the royal school of pages (Königliche Pageker), and in 1814 was appointed lieutenant in the regiment of Bavarian life-guards. With it he took part in the short campaign in France of 1815, being in bivouac for several months near Mannheim and in the department of the Yonne. He saw no fighting, however, and returned home with his regiment towards the close of the same year. Possessed of an intense desire for study, and finding garrison life distasteful and irksome, he obtained a long leave of absence, and after a tour in Switzerland and the Bavarian Alps, entered the university of Würzburg in 1818 as a student of philosophy and philology. In the following year he migrated to that of Erlangen, where he sat at the feet of F. W. J. von Schelling, and became one of his defined plateaus have steep flanks in contrast with Oriental studies. He published a little volume of poems—Ghasaden (1821), each consisting of ten to twenty verses, in which he imitates the style of Rückert; Lyrische Blütler (1821); Spiegel der Hais (1822); Vermischte Schriften (1822); and Neue Ghasaden (1823). These productions attracted the attention of eminent men of letters, among them Goethe, both by reason of their contents, which breathe the spirit of the East, and also of the purity and elegance
of their form and diction. Though he was at first influenced by the school of Romanticism, and particularly by Spanish models, yet the plays written during his university life at Erlangen, Der glückl. Pionier, Der Schatz des Rhamstadt, Beregara, Treue und Treue, Dr. Turn mit seien Pforten, show a clearness of plot and expression foreign to the Romantic style. His antagonism to the literature of his day became more and more pronounced, and he ventured his indignation at the want of art shown by the later Romanticists, the inanity of the lyricists, and the bad taste of the so-called fate tragedies (Schicksalstragödien), in the witty "Aristophanes" comedies Die verhängnisvolle Gabel (1826) and Der romantische Odipus (1828).

The want of interest, amounting even to hostility, with which Platen's enthusiasm for the purity and dignity of poetry was received in many literary circles in Germany increased the poet's indignation. The small success of his plays, however, which he hitherto made his home, living at Florence, Rome and Naples. His means were slender, but, though frequently necessitous, he felt happy in the life he had chosen, that of a "wandering rhapsodist." Der romantische Odipus earned for him the bitter enmity of Karl Immermann and Heinrich Heine, and in the literary feud which ensued Heine launched the most baseless calumnies at the poet, which had the effect of prejudicing public opinion against him. But he retained many staunch admirers, who delighted in the purity of the subject matter of his productions and their beauty of form and diction. In Naples, where he formed the friendship of August Kopisch, the poet and painter, were written his last drama Die Liga von Cambray (1832) and the delightful epic fairy-tale Die Abbassiden (1836; 1834), besides numerous lyrical poems, odes and ballads. He also essayed historical work in a fragment, Geschichten des Königreichs Neapel (1838), without, however, achieving any marked success. In 1832 his father died, and after an absence of eight years Platen returned to Germany for a while, and in the winter of 1833-1834 lived at Munich, where he revised the first complete edition of his poems, Gedichte (1833). In the summer of 1834 he returned to Italy, and, after living in Florence and Naples, proceeded in 1835 to Sicily. Dread of the cholera, which was at that time very prevalent, induced him to move from place to place, and in November of that year he was taken ill at Syracuse, where he died on the 5th of December 1835. Like Heine himself, Platen failed in the drama, but his odes and sonnets, to which must be added his Polniederl (1831), in which he gives vent to his warm sympathy for the Poles in their rising against the rule of the Tsar, are in language and metre so artistically finessed as to rank among the best classical poems of modern times.

Platen's Gesammelte Werke were first published in one volume in 1839, and have been frequently reprinted; a convenient edition is that edited by K. Gotzkowsky in 1850, Geschichte der Italiener, which he hitherto made his home, living at Florence, Rome and Naples. His means were slender, but, though frequently necessitous, he felt happy in the life he had chosen, that of a "wandering rhapsodist." Der romantische Odipus earned for him the bitter enmity of Karl Immermann and Heinrich Heine, and in the literary feud which ensued Heine launched the most baseless calumnies at the poet, which had the effect of prejudicing public opinion against him. But he retained many staunch admirers, who delighted in the purity of the subject matter of his productions and their beauty of form and diction. In Naples, where he formed the friendship of August Kopisch, the poet and painter, were written his last drama Die Liga von Cambray (1832) and the delightful epic fairy-tale Die Abbassiden (1836; 1834), besides numerous lyrical poems, odes and ballads. He also essayed historical work in a fragment, Geschichten des Königreichs Neapel (1838), without, however, achieving any marked success. In 1832 his father died, and after an absence of eight years Platen returned to Germany for a while, and in the winter of 1833-1834 lived at Munich, where he revised the first complete edition of his poems, Gedichte (1833). In the summer of 1834 he returned to Italy, and, after living in Florence and Naples, proceeded in 1835 to Sicily. Dread of the cholera, which was at that time very prevalent, induced him to move from place to place, and in November of that year he was taken ill at Syracuse, where he died on the 5th of December 1835. Like Heine himself, Platen failed in the drama, but his odes and sonnets, to which must be added his Polniederl (1831), in which he gives vent to his warm sympathy for the Poles in their rising against the rule of the Tsar, are in language and metre so artistically finessed as to rank among the best classical poems of modern times.

same locality, though brought by way of Jamaica; and it was he who first described it in 1750 as a new metal. Native platinum was discovered in 1808 in gold workings of Wollaston's, in the Urals, but it was not until 1822 that its true nature was recognized. The chief Russian localities are in the districts of Nižnij Tagilsk and Gorobłagodatsk, where it is found in shallow drift deposits, containing pebbles of serpentine, which represent the original matrix. The last district has acquired importance in recent years. Although the platinum-bearing gravels usually contain a very small proportion of the metal, the average in 1895 being only 0.13% to the ton, rich discoveries have occasionally been made in the history of the workings, and nuggets of exceptional size have been unearthed. The largest recorded specimens are one of 350 oz. from Nižnij Tagilsk, and another of 724 oz. from the Gorobłagodatsk district.

In 1831 platinum ore was recognized in the gold-bearing deposits of Borneo, where it had previously been regarded as worthless, being known to the natives as mas kodok (frog gold). Although recorded from various parts of the island, its occurrence seems to be definitely known only in Tanah-Laut, in the south-east of Borneo. In Australia platinum ore has been found near Fīnīfīld (near Condobolin), New South Wales; whilst in New Zealand it occurs in sands and gravels in the Thames gold-field, the Takaka River and the Gorge River flowing into Awarua Bay. Many localities in North America have yielded platinum, generally in beach sands or in auriferous alluvia, and in some cases the deposits are of commercial importance. The metal is found in Alaska, British Columbia, Oregon (Douglas county) and California (Butte county, Trinity county, Del Norte county). It has been recorded also from the states of New York and North Carolina. In a nickelliferous sulphide ore worked at Sudbury, in Ontario, platinum has been discovered in the form of an arsenide (Pt As), which has been called sperrylite by H. L. Wells, who analysed it in 1889, and named it after F. L. Sperry, of Sudbury. It belongs to the pyrites group, and is interesting as being the only known mineral in which platinum occurs in combination except as alloy.

Native platinum seems to be a mineral of rather wide distribution, but very in sparse quantity. The sands of the Rhine, derived from Alpine rocks, have been found to contain platinum in the proportion of 0-0004%. It has also been found in the sands of the Ivalo River in Lapland; it is recorded from Röros in Norway; and it was detected by W. Mallet in some of the gold-sands of the streams in Co. Wicklow, Ireland.

The table shows the official amount (in ounces Troy) of platinum produced in Russia for certain years, the actual amounts are much larger:

(Rothwell's Mineral Industry, 1908.)

Platinum is largely used for the manufacture of chemical apparatus, incandescent lamps, thermo-couples; in the manufacture of sulphuric acid by the contact process, in photography, and in jewelry. The price of the metal has risen considerably, not so much on account of the restricted supply, but chiefly because the sources of supply have passed into the hands of a few individuals. The following data show the fluctuations in the average price of platinum ingot per ounce Troy:

Platinum may be extracted from its ore by both wet and dry processes. In the latter method, due to H. Sainte-Clare-Deville and H. J. Debray, the ore is smelted in a furnace constructed of two blocks of lime, and the metallic button so obtained is re-melted in a reverberatory furnace with galena or litharge, the lead alloy platinum being then copered, and the platinum fused into an ingot by remelting in a furnace (see Dugler's Polytech., 1853, p. 85; 1859, p. 54; 1883, p. 206). The platinum is then obtained by Wollaston's wet method the ore is dissolved in aqua regia, the osmiridium, ruthenium and rhodium being left unattacked, and the double chloride of gold and platinum precipitated by ammonium chloride in the presence of an excess of acid. The double chloride is then washed, dried and ignited, leaving a residue of metal. G. Matthey (Chem. News, 1879, 39, p. 175) obtains pure platinum by washing the metal by removing the excess of acid with a large excess of lead. The lead alloy is then treated with a dilute nitric acid and the insoluble portion taken up in dilute aqua regia. From the solution so obtained lead is precipitated as sulphate, and the double chloride of gold and rhodium as double chloride is then removed by extraction with water, and the residue of finely divided platinum remains. The German firm of Hersch (in Hanover) heat the raw ore with aqua regia and water under pressure, evaporate the solution to dryness, and heat the residue to 125°C. A clear aqueous extract of the residue is then acidified with hydrochloric acid and precipitated with ammonium chloride. The double chloride is ignited and the finely divided platinum so obtained is fused in the oxyhydrogen blowpipe.

Platinum is a greyish-white metal which is exceedingly malleable and ductile; the addition of a small quantity of iridium hardens it and diminishes its ductility very considerably. Its specific gravity is 20-85 to 21-71, and its mean specific heat from 0 to 100°C is 0-0323 (J. Viole, Comptes rendus, 1877, 85, p. 543); W. F. White (Amer. Jour. Sci., 1899, IV, 28, p. 341) gives the general formula: \( s = 0-055 \times 10^{-6} \times T \). Specific heat at 0°C. Its temperature of fusion is in the neighbourhood of 1700 to 1800°C, various intermediate values having been obtained by different investigators (see J. A. Harker, Chem. News, 1905, 91, p. 262; C. Féry and C. Chéneveau, Comptes rendus, 1909, 148, p. 401; also C. W. Waidner and G. H. Burgess, ibid., 1909, 148, p. 1177). Its latent heat of fusion is 27-18 calories (Viole, loc. cit.). The metal has been obtained in the crystalline condition by distillation in the electric furnace, or by decomposing its fluoride at a red heat (H. Moissan). Platinum, like palladium, absorbs large quantities of hydrogen and other gases, the occluded gas then becoming more "active"; for this reason platinum is used largely as a catalytic agent. The alloy of the greatest value in this respect is that obtained by dissolving in the nitric acid form, may be obtained. Spongy platinum is produced when ammonium platinocloride is ignited; platinum black on the reduction of acid solutions of platinum salts; and colloidal platinum by passing an electric arc between two platinum wires under the surface of pure water (G. Bredig, Zeit. phys. Chem., 1901, 37, pp. 1, 323). Platinum is practically oxidizable; it combines directly with phosphorus, arsenic, antimony, silicon, boron, and fluorine, and with almost all other metals. It is practically unattacked by all acids, dissolving only in aqua regia or in mixtures which generate chlorine. When fused with alkali hydroxides in the presence of air it forms platinites. It is readily attacked by fused nitrates, and by potassium cyanide and hydrocyanic acid. All the platinites compounds when heated strongly decompose, and leave a residue of the metal. Of platinum salts, in the true sense of the word, none exist; there is no carbonate, nitrate, sulphate, &c; halide salts, however, are known, but are obtained in an indirect manner.

Platinum monoxide, PtO, obtained by heating the corresponding hydrate, is a dark-coloured powder which is easily reduced to the metal (L. Wöhler, Ber., 1901, 35, p. 3478). The hydrated form, PtO₂·H₂O, is obtained by adding caustic soda, or by adding caustic soda to a boiling solution of platinum nitric acid, K₂PtCl₆, the precipitate being rapidly washed and dried in vacuo (L. Wöhler, Zeit. anorg. Chem., 1903, 48, p. 1). Koch prepared it as a black powder when freshly prepared in concentrated acids, but when dried it is insoluble. It is an acidic oxide, the dioxide being both acidic and basic. It behaves as a strong oxidizing and reducing agent, C. Engler and L. Wöhler (Zeit. anorg. Chem., 1901, 9, p. 1), have shown that the oxygen from the dioxide, containing oxidized oxygen, is soluble in dilute hydrochloric acid and also liberates iodine from potassium iodide, and that the ratio between the amount of platinum dissolved and the amount of oxygen oxidized agrees with the formation of a compound corresponding to the formula PtO. Platinum dioxide (platinic
oxide), PtO₂·2H₂O, is obtained by adding an excess of caustic soda solution to a boiling solution of chloroplatinic acid, the hot solution being diluted and neutralized with acetic acid. It loses its water of hydration on standing. It is not decomposed by platinocyanides on heating. PtO₂·2H₂O forms a white or yellowish powder which is readily hydrated. The hydrated forms of composition, PtO₂·2H₂O and PtO₂·H₂O, have been described. (E. Prost, Bull. soc. chim., 1886, 49, p. 136; H. Topsoe, Ber., 1895, 28, p. 2171). The term hydrate is here used to denote the compound, Pt(OH)₄·2H₂O, for salts are known (namely the platinates) corresponding to it, those of the alkali metals being soluble in water, and possessing an alkaline reaction (M. Blondel, Ann. chim. phys., 1872, 6, p. 406). In many similar cases, however, it is also known, the chlorine replacing one or more hydroxyl groups and giving rise to complexes of composition, H₂PtCl₆(OH)₂, H₂PtCl₆(OH)₃, H₃PtCl₆(OH)₃, and H₄PtCl₆(OH)₄. The platinates are entirely soluble in water, and are readily dissolved in cold, and are readily reduced to the metallic condition. They give with sulphotetradecyl hydrogen a dark brown precipitate, soluble in excess of ammonium sulphide. Potassium iodide gives a brown solution with gradual formation of a precipitate. When the characteristic precipitate is formed, it precipitates with potassium and ammonium chlorides. The platinates are yellow or colourless solids which, when boiled with hydrochloric acid, give a dark brown precipitate of platinum sulphide, and with heating, readily form a solution of platinic iodide, PtI₄. Platinum tetroxide, PtO₂, is obtained as K₂O₂·PtO₂ by electrolyzing a solution of platinic hydride in potash, this compound is obtained, giving the solution a brown, as a easily decomposable powder (L. Walker and F. Martin, Ber., 1869, 42, p. 3326).

Platinum bichloride, PtCl₂·2H₂O is obtained by heating chloroplatinic acid with aqueous hydrogen peroxide (J. L. Bertele and P. Schützenberger, Ann. chim. phys., 1890, 15, p. 95; Ber., 1890, 23, p. 61). It is a yellow powder, characteristic of a double salt, platinum bichloride combines with carbon monoxide, yielding compounds of composition, PtCl₂·CO, PtCl₂·2CO, 2PtCl₂·3CO (J. Schützenberger, Ann. chim. phys., 1890, 15, pp. 95, 97; Ber., 1890, 23, p. 61). PtCl₂·CO is only known in solution, and as such is obtained when platinum bichloride is dissolved in hydrochloric acid, or by decomposing the barium salt with sulphuric acid, or the silver salt with hydrochloric acid. When the solutions are obtained by reducing the chloroplatinates or directly from the acid itself. They are mostly soluble in water giving red solutions. The solution readily oxidized, and a resultant hydrogen replaces it to metallic platinum. Potassium platinchloride or chlorarachne, K₂PtCl₆·2H₂O is prepared by reducing hydrogen chloroplatinichloride with sulphur dioxide, or potassium platinchloride with potassium oxalate in the presence of iron. It is a brown powder (R. Klauditz, Ber., 1910, 43, p. 764). By adding potassium chloride to a solution of platinum bichloride in hydrochloric acid. It crystallizes in dark red prisms, is readily soluble in water, but insoluble in alcohol. The solution of the free acid is reduced by carbon in solution or by HCl·PtCl₆·2H₂O. When the free acid is reduced by alcohol, or when ethylene is passed into a solution of platinum bichloride in hydrochloric acid, PtCl₂·CH₄ is obtained as a brown amorphous mass. This is a solution of the acid, H₂PtCl₆·2H₂O. The bichloride also combines with phosphine to form PtCl₂·2P₂Cl₆. Platinic chloride, PtCl₅, is obtained when chloroplatinic acid is heated in a current of dry hydrochloric acid gas to 185° C. (W. P. Simons and A. E. Harkins, J. Am. chem. Soc., 1910, 32, p. 1195). It is a yellow-white powder, the chloroplatinic acid at 275° C. (A. Rosenheim and W. Lüwenstern, Zeit. anorg. Chem., 1903, 37, p. 394). It forms a reddish brown crystalline mass. It is very hygroscopic. Numerous hydrates are known. The chloride is characterized by the readiness with which it forms double salts with the metallic chlorides and with the hydrochlorides of most organic bases. Chloroplatinic acid, H₂PtCl₆·6H₂O, is obtained by the direct action of the acid on the metallic hydroxides or carbonates, and are usually of an orange or yellow colour and are mostly soluble in water. Potassium platinchlorate, K₂PtCl₆, is obtained, in the form of a yellow crystalline precipitate, when a concentrated solution of a potassium salt is added to a solution of chloroplatinic acid. It crystallizes in octahedra which are scarcely soluble in water, and practically insoluble in absolute alcohol. It decomposes at a red heat into platinum, chlorine and potassium chloride. The corresponding ammonium salt is less soluble in water. It is decomposed by heat. The ammonium salt, (NH₄)₂PtCl₆ resembles the potassium salt in its solubility in water and in alcohol. Corresponding compounds of numerous other elements are of the same nature (M. G. Moissan, Ann. chim. phys., 1894, 6, 24, p. 282) by the action of fluorine on platinum at 500-600° C. They may be separated by taking advantage of the different solubilities in water.

Platinum monosulphide, PtS, is obtained is the direct union of platinum and sulphur; by heating ammonium chloroplatinate with sulphur; or by the action of sulphuretted hydrogen on the chloroplatinic acid. It is a dark brown, slightly soluble in water, and insoluble in aqua regia. It decomposes when heated strongly leaving a residue of metallic platinum, the same reduction taking place at comparatively low temperatures when it is heated in a current of hydrogen (C. P. Chauvet, Ann. chim. phys., 1889, 138, p. 604; 1873, 148, p. 633; 1873, 149, p. 381). A salt of composition, Pt(OH)₄·H₂SO₄·H₂O, has been prepared by M. Dulau and J. R. G. Lacrozet, C. rendus, 1889, 108, p. 381) by the solution of the hydride H₂Pt(OH)₂, i.e. PtO₂·H₂O, in dilute sulphuric acid at 0° C. On the addition of cold concentrated sulphuric acid to the solution so obtained, the above salt is precipitated in the form of minute needles, which gradually decompose in the concentrated sulphuric acid. These droplets are heated with sulphuretted hydrogen to 60° C. The precipitate must be washed and dried in vacuo, since it oxidizes rapidly on exposure to air. It is a black powder, which when heated strongly in air decomposes and leaves a residue of platinum, but if heated in absence of air leaves a residue of the monosulphide. Sulphides of composition PtS₁₁ (L. G. Schutzenberger, C. rendus, 1886, 103, p. 603; 1886, 105, p. 3) and PtS₁₁·H₂O (A. Colonna, Ann. chim. phys., 1886, 105, p. 3) have also been obtained. A Platinium sulphate, Pt₃(SO₄)₂·H₂O, has been obtained by L. Stuchlik (Ber., 1904, 37, p. 2973) by the action of sulphuric acid (s.g. 1.84) under the influence of an alternating current. A crystalline precipitate is obtained, which is soluble in water and is very hygroscopic.

The Platinonitriles of composition M₃Pt(N₃)₄ are mostly obtained by double decomposition from the potassium salt, which is formed by the action of nitric acid on platinum and potassium nitrate, or by the addition of potassium nitrate to a solution of the hexaammine chloride. A hexaammine is formed by the action of ammonium hydroxide on potassium nitrate and hydrogen. A hexaammine is formed by the action of ammonium hydroxide on potassium nitrate and hydrogen. It is a white, or yellowish precipitate, which is insoluble in water, and is very hygroscopic. The Platinonitriles of composition M₃Pt(N₃)₄ are mostly obtained by double decomposition from the potassium salt, which is formed by the action of nitric acid on platinum and potassium nitrate, or by the addition of potassium nitrate to a solution of the hexaammine chloride. A hexaammine is formed by the action of ammonium hydroxide on potassium nitrate and hydrogen. A hexaammine is formed by the action of ammonium hydroxide on potassium nitrate and hydrogen. It is a white, or yellowish precipitate, which is insoluble in water, and is very hygroscopic.

Platinum cyanide, Pt(N₃)₂, is formed by the addition of mercuric cyanogen, or a solution of hydrocyanic acid, to a solution of platinum. Platinum, or by the addition of mercury or ammonium platinocyanide by heat. It is an amorphous powder which is insoluble in water, acids or alkalis, but is soluble in a solution of hydrocyanic acid. It burns when heated. The latter are known as platinocyanides. They are derived from the acid H₂Pt(N₃)₂ by the decomposition of mercury or copper salt with sulphuretted hydrogen, or of the barium salt with sulphuric acid. It crystallizes from water in cinnamon-red prisms with metallic luster. A red precipitate is obtained in the solution of the red precipitate when heated in an acetic acid solution. The red precipitate is formed when heated in an acetic acid solution. It is an amorphous powder which is insoluble in water, acids or alkalis, but is soluble in a solution of hydrocyanic acid. It burns when heated.
Barium platinocyanide, $\text{BaPt(CN)}_4\cdot 4\text{H}_2\text{O}$, is prepared by the action of baryta water on the copper salt; by dissolving platinum in baryta cyanide under the influence of an alternating current; by the simultaneous action of hydrocyanic and sulphurous acids on a mixture of baryta and chlorplatinic acid (P. Bergsog, Zeit. anorg. Chem., 1899, 19, p. 318). It crystallizes in yellow monoclinic prisms and is soluble in hot water. It is employed for the manufacture of fluorescent screens used for the detection of X-rays.

The platinum salts combine with ammonia to form numerous derivatives which cannot be considered as salts of characteristic base. The first compound of this type was isolated in 1828 by Magnus, who obtained a green salt by the action of ammonia on platinum bichloride. Two series of these salts are known, one in which the metal corresponds to bivalent platinum, the other in which it corresponds to tetravalent platinum. The general formulae of the groups in each series are shown below, the method of classification being that due to Werner.

In the above table X represents a monovalent acid radical and R a monovalent radical, radicals of properties analogous to those of the hydroxyl radical. The first of these series was examined by F. T. Cievé, Bull. soc. chem. 1867 et seq.; S. M. Jørgensen, Journ. prak. Chem. 1877 et seq.; C. W. Blomstrand, Ber. 1871 et seq.; and A. Werner, Zeit. anorg. Chem., 1893 et seq. A most valuable account of the metal-ammonia compounds is given by W. L. H. L. Seubert (Ann. 1888, 207, p. 1; Ber. 1888, 21, p. 2179) by analyses of ammonium and potassium platinocyanides, the value 194.86 being obtained.

**PLATO**, the great Athenian philosopher, was born in 427 B.C., and lived to the age of eighty. His literary activity may be roughly said to have extended over the first half of the 4th century B.C. His father's name was Aristocles, and his mother's family, which claimed descent from Solon, included Critias, one of the thirty tyrants, and other well-known Athenians of the early 4th century B.C. That throughout his early manhood he was the devoted friend of Socrates, that in middle life he taught those who resorted to him in the grove named Academus, near the Cephissus, and that he founded the first great philosophical school, that (with alleged interruptions) he continued to preside over the Academy until his death, are matters of established fact. It is said by Aristotle that he was at one time intimate with Cratylos the Heraclean. Beyond this we have no authentic record of his outward life. That his name was at first Aristocles, and was changed to Plato because of the breadth of his shoulders or of his style or of his forehead, that he wrestled well, that he wrote poetry which he burnt on hearing Socrates, fought in three great battles, that he had a thin voice, that (as is told of other Greek philosophers) he travelled to Cyrene and conversed with priests in Egypt, are statements of Diogenes Laërtius, which rest on more or less uncertain tradition. The express assertion— which this author attributes to Hermiodorus—that after the death of Socrates Plato and other Sophists took refuge with Euripides, at Athens, has no stronger claim to authenticity. But the fact cannot be regarded as certain, still less the elaborate inferences which have been drawn from it. The romantic legend of Plato's journeys to Sicily, and of his relations there with the younger Dionysius and the prinely but unfortunate Dion, had obtained some degree of consistency before the age of Cicero, and at an unknown but probably early time was worked up into the so-called *Epistles* of Plato, now all but universally discredited. Nor is there sufficient ground for supposing, as some have done, that an authentic tradition is perceptible behind the myth.

The later years of the Peloponnesian War witnessed much mental disturbance and restlessness at Athens. More than at any time since the age of Cleisthenes, the city was divided, and a man's foes were often men of his own tribe or deme. Contention in the law-courts and rivalries in the assembly had for many years men a more absorbing interest than questions of peace and war. Hereditary traditions had relaxed their hold, and political principles were not yet formulated. Yet there was not less scope on this account for personal ambition, while the progress of democracy, the necessity of conciliating the people, and the apportionment of public offices by lot had a distracting and, to reflecting persons, often a discouraging effect. For those amongst whom Plato was brought up this effect was aggravated by the sequel of the oligarchical revolution, while, on the other hand, for some years after the restoration of the democracy, a new stimulus had been imparted, which, though of short duration, was universally felt.

These events appear in two ways to have encouraged the diffusion of ideas. The ambitious seem to have welcomed them as a means of influence, while those who turned from public life were more stimulated to speculative dispute. However this may have been, it is manifest that before the beginning of the 4th century B.C. the intellectual atmosphere was already charged with a new force, which although essentially one may be differently described, according to the mode of its development, as (1) rhetorical and (2) theoretical and "sophistical." This last word indicates the channel through which the current influences were mostly derived. A new want, in the shape both of interested and of disinterested curiosity, had insensibly created a new profession. Men of various fatherlands, some native Athenians, but more from other parts of Hellas, had set themselves to supplement the deficiencies of ordinary education, and to train men for the requirements of civic life. More or less consciously they based their teachings on the philosophical dogmas of an earlier time, when the speculations of Xenophon, Heraclitus or Parmenides had interested only a few "wise men." Those great thoughts were now to be expounded, so that "even cobblers might understand." The self-appointed teachers found a rich field and abundant harvest among the wealthier youth, to the chagrin of the old-fashioned Athenian, who sighed with Aristophanes for the good old days when men knew less and listened to their elders and obeyed the customs of their fathers. And such distrust was not wholly unfounded. For, amidst much that was graceful and improving, these novel questionings had an influence that, besides being unsettling, was aimless and unreal. A later criticism may discern in them the two great tendencies of naturalism and humanism. But it may be doubted if the sophist was himself aware of the direction of his own thoughts. For, although Prodicus or Hippias could debate a thesis and moralize with effect, they do not appear to have been capable of speculative reasoning. What passed for such was often either verbal quibbling or the pushing to an extreme of some isolated abstract notion. That *prudens quaecumque* which is *dimidium scientiae* had not yet been put. And yet the hour for putting it concerning human life was fully come. For the sea on which men were drifting was profoundly troubled, and would not sink back into its former calm. Conservative reaction was not less hopeless than the dreams of the poets were unwavering. In a random talk, with gay, irresponsible energy, the youth were debating problems which have exercised great minds in Europe through all after time.

Men's thoughts had begun to be thus disturbed and eager when Socrates (q.v.) arose. To understand him is the most necessary preliminary to the study of Plato. There is no reason to doubt that...
the general truth of the assertion, which Plato attributes to himself in the Apologie, that he felt a divine vocation to examine men by questioning other men. He was really doing for Athenians, whether they would or no, what the sophist professed to do for his adherents, and what such men as Protagoras and Prodicus had actually done in part. One obvious difference was that he would take no fee. But there was another and more deep-lying difference, which distinguished him not only from the contemporary sophists but from the thinkers of the previous age. This was the Socratic attitude of inquiry. The sceptical movement had confused men's notions as to the value of ethical ideas. If "right" is one thing in Athens and another in Sparta, why strive to follow right rather than expediency? The laws put restraint on nature, which is prior to them. Then why submit to law? And the ingenuities of rhetoric had stirred much unwarranted discussion. Every case seemed capable of being argued in opposite ways. Even on the great question of the ultimate constitution of things, the conflicting theories of absolute immutability and eternal change appeared to be equally irreconcilable and equally untenable. Men's minds had been confused by contradictory voices—one crying "All is motion," another "All is rest!" one "The absolute is unattainable," another "The relative alone is real!" some upholding a vague sentiment of traditional right, while some declared for arbitrary convention and some for the law "of nature." Some held that virtue was spontaneous, some that it was due to training, and some paradoxically denied that either vice or falsehood had any meaning. The faith of Socrates, whether instinctive or inspired, remained untroubled by these jarring tones. He did not ask "Is virtue a reality?" or "Is goodness a delusion?" But, with perfect confidence that there was an answer, he asked himself and others "What is it?" (r. 173a) or, more particularly, as Xenophon states: "What is a state? What is a statesman? What is just? What is unjust? What is government? What is it to be a ruler of men?" This form of question, however simple, the originality of Socrates is typified; and by means of it he laid the first stone, not only of the fabric of ethical philosophy, but of scientific method, at least in ethics, logic and psychology. Socrates never doubted that if men once knew what was best, they would also do it. They erred, he thought, from not seeing the good, and not because they would not follow it. If seen. This is expressed in the Socratic dictum: "Virtue is Ignorance." "Virtue is knowledge." This lifelong work of Socrates, in which the germ of ethics, psychology and logic were contained, was idealized, developed, dramatized—first embodied and then extended beyond its original scope—in the writings of Plato, which may be described as the literary outcome of the profound impression made by Socrates upon his greatest follower. These writings (in pursuance of the importance given by Socrates to conversation) are all cast in the form of imaginary dialogue. But in those which are presumably the latest in order of composition this imaginative form interferes but little with the direct expression of the philosopher's own thoughts. The many-coloured veil at first inseparable from the features is gradually worn thinner, and at last becomes almost imperceptible.

Plato's philosophy, as well as his method of presentation, is at once an intellectual and a mystical aspect; and both are dominated by a pervading ethical motive. In obeying the Dialogues. Socratic impulse, his speculative genius absorbed and harmonized the various conceptions which were present in contemporary thought, bringing them out of their dogmatic isolation into living corroboration with one another, and with the life and experience of mankind. His poetical feeling and imagination, taking advantage of Pythagorean and Orphic suggestions, surrounded his abstract reasonings with a halo of mythology which made them more fascinating, but also more difficult for the prosaic intellect to comprehend. Convinced through the conversations of Socrates that truth and good exist and that they are inseparable, persuaded of the unity of virtue and of its dependence upon knowledge, he set forth upon a course of inquiry, in which he could not rest until the discrepancies of ordinary thinking were not only exposed but accounted for, and resolved in relation to a comprehensive theory. In this "pathway towards reality," from the consideration of particular virtues he passed to the contemplation of virtue in general, and thence to the nature of universals, and to the unity of knowledge and being. Rising still higher on the road of generalization, he discussed the problem of unity and diversity, the one and the many. But in these lofty speculations the facts of human experience were not lost to view. The one, the true, the good, is otherwise regarded by him as the moral ideal, and this is examined as realized both in the individual and in the state. Thus ethical and political speculations are combined. And as the method of inquiry is developed, the leading principles both of logic and of psychology become progressively more distinct and clear. Notwithstanding his high estimate of mathematical principles, to him the type of exactness and certitude, Plato contributed little directly to physical science. Though he speaks with sympathy and respect of Hippocrates, he had no vocation for the patient inductive observation of natural processes, through which the Greek physicians, though they obtained few lasting results, yet founded a branch of science that was destined to be beneficently fruitful. And he turned scornfully aside from the Atomists, Leucippus and Democritus, whose first principle, the basis of so much in modern physics, appeared to him to be tainted with materialism. Yet his discursive thought, as in later years he held high intercourse with Archytas and other contemporary minds, could not fail, unlike his master's, to include a theory of the Cosmos in its purview. In this regard, however, the poet-philosopher brought imagination to the aid of reason, thus creating a new mythology, of which the Timaeus is the most conspicuous example.

Amidst great diversity, both of subject and of treatment, Plato's dialogues are pervaded by two dominant motives, a passion for human improvement and a persistent faith in the power and supremacy of mind. What is commonly known as his doctrine of Ideas is only one phase in a continuous progress towards the realization of a system of philosophy in which the supreme factor is reason guiding will. But the objectivity, which from the first was characteristic of all Greek thinking, and his own power of poetic presentation, obscured for a time, even for Plato himself, the essential spirituality of his conceptions, and at one time even threatened to arrest them at a stage in which the universal was divorced from the particular, the permanent from the transient, from becoming, and in which the first principles of reality were isolated from one another as well as from the actual world. Gradually the veil was lifted, and the relation between the senses and the intellect, phenomena and general laws, the active and the contemplative powers, came to be more clearly conceived. The true nature of abstraction and generalization, and of predication and inference, began to be discerned, and speculation was verified through experience. The ideas were seen as categories, or forms of thought, under which the infinite variety of natural processes might be comprised. And thus the dialogues present, as in a series of dissolving views, a sort of model or compendium of the history of philosophy. Plato's methods are nowhere distinctly formulated; nor are the directions he gives forward in his dialogues always consistent with each other, but much especially of his later thought is systematized, and as it were crystallized in the treatises of Aristotle; by whom the point of view which Plato had approached, but not finally attained, was made the starting-point for more precise metaphysical determinations and carried into concrete theories having the stamp of a more rigid logical method. The departments of ethics and politics, of dialectic and of psychology, of physics and metaphysics, thus came to be more clearly distinguished, but something was lost of the unity and intensity of spiritual insight which had vitalized these various elements, and fused them in a dynamic harmony.

The student of philosophy, whatever may be the modern system to which he is most inclined, sensational, intuitive, conception, transcendental, will find his account in returning
to this well-spring of European thought, in which all previous movements are absorbed, and from which all subsequent lines of reflection may be said to diverge. As was observed by Jowett (St. Paul, 1855), "the germ of all ideas, even of most Christian ones, are to be found in Plato."

Two great forces are persistent in Plato: the love of truth and zeal for human improvement. In the period culminating with the Republic, these two motives, the speculative and the practical, are combined in one harmonious working. In the succeeding period, without excluding one another, they operate with alternating intensity. In the varied outcome of his long literary career, the metaphysical "doctrine of ideas" which has been associated with Plato's name underwent many important changes. But pervading all these there is the same constant belief in the supremacy of reason and the identity of truth and good. From that abiding root spring forth a multitude of thoughts concerning the mind and human things—turning chiefly on the principles of psychology, education and political reform—thoughts which, although unverified, and often needing correction from experience, still constitute Plato the most fruitful of philosophical writers. While general ideas are powerful for good or ill, while abstractions are necessary to science, while mankind are apt to crave after perfection, and ideals, either in art or life, have an acknowledged value, so long the renown of Plato will continue. "All philosophic truth is Plato rightly divined; all philosophic error is Plato misunderstood"—is the verdict of one of the keenest of modern metaphysicians.

Plato's followers, however, have seldom kept the proportions of his teaching. The diverse elements of his doctrine have survived the spirit that informed them. The pythagorean mysticism of the Timaeus has been more prized than the subtle and clear thinking of the Theaetetus. Logical inquiries have been hardened into a barren ontology. Semi-mythical statements have been rationalized literally and mystical fancies perpetuated without the genuine thought which underlay them. A part (not the essential part) of his philosophy has been treated as the whole. But the influence of Plato has extended far beyond the limits of the Platonic schools. The debt of Aristotle to his master has never yet been fully estimated. Zeno, Chrysippus, Epicurus borrowed from Plato more than they knew. The moral ideal of Plutarch and that of the Roman Stoics, which have both so deeply affected the modern world, could not have existed without him. Neopythagoreanism was really a crude Neoplatonism. And the Sceptics availed themselves of weapons either forged by Plato or borrowed by him from the Sophists. A wholly distinct line of infiltration is suggested by the mention of Philo and the Alexandrian school (cf. section in Arabian Philosophy, ii. 262e, 9th edition), and of Clement and Origen, while Gnostic heresies and even Talmudic mysticism betray perversions of the same influence. The effect of Hellenic thought on Christian theology and on the life of Christendom is a subject for a volume, and has been pointed out in part by E. Zeller and others (cf. Neoplatonism). Yet when Plotinus in the 3rd century (after hearing Ammonius), amidst the revival of religious paganism, founded a new spiritualistic philosophy upon the study of Plato and Aristotle combined, this return to the fountain head had all the effect of novelty. And for more than two centuries, from Plotinus to Proclus, the great effort to base life anew on the Platonic wisdom was combined. But it was rather the ghost than the spirit of Plato that was so "unhindered."

Instead of striving to reform the world, the Neoplatonist sought after a retired and cloistered virtue. Instead of vitalizing science with fresh thought, he lost hold of all reality in the contemplation of infinite unity. He had skill in dealing with abstractions, but laid a feeble hold upon the actual world.

"Hermes Trismegistus" and "Dionysius Areopagita" are names that mark the continuation of this influence into the middle ages. The pseudo-Dionysius was translated by Erigena in the 9th century.

Two more "Platonic" revivals have to be recorded—

Florence in the 15th and at Cambridge in the 17th century. Both were enthusiastic and both uncritical. The translation of the dialogues into Latin by Marsilio Ficino was the most lasting effect of the former movement, which was tinged with the unscholarly ardour of the Renaissance. The preference still accorded to the Timaeus is a fair indication of the tendency to bring fumum ex fulgere which probably marred the discussions of the Florentine Academy concerning the "chief good." The new humanism had also a sentimental cast, which was alien from Plato. Yet the effect of this spirit on art and literature was very great, and may be clearly traced not only in Italian but in English poetry.

The "Cambridge Platonists" have been described by Principal Tulloch in his important work on Rational Theology in England in the 17th century, and again by Professor J. A. Stewart in the concluding chapter of his volume on the Myths of Pluto. Their views were mainly due to a reaction from the philosophy of Hobbes, and were at first suggested as much by Plotinus as by Plato. It is curious to find that, just as Socrates and Ammonius (the teacher of Plotinus) left no writings, so Whitchote, the founder of this school, worked chiefly through conversation and preaching. His pupils exercised a considerable influence for good, especially on English theology; and in aspiration if not in thought they derived something from Plato, but they seem to have been incapable of separating his meaning from that of his interpreters, and Cudworth, their most consistent writer, was at once more systematic and less scientific than the Athenian philosopher. The translations of Sydenham and Taylor in the 18th century and the beginning of the 19th are proofs of the continued influence of Platonism in England.

The critical study of Plato begins from Schleiermacher, who did good work as an interpreter, and tried to arrange the dialogues in the order of composition. His attempt, which, like many efforts of constructive criticism, went far the wrong way as it was possible, was vitiated by the ground-fallacy of supposing that Plato had from the first a complete system in his mind which he partially and gradually revealed in writing. At a considerably later time Karl Friedrich Hermann, to whom all students of Plato are indebted, renewed the same endeavour on the far more plausible assumption that the dialogues faithfully reflect the growth of Plato's mind. But he also was too sanguine, and exaggerated the possibility of tracing a connexion between the outward events of Plato's life and the progress of his thoughts. This great question of the order of the dialogues, which has been debated by numberless writers, is one which only admits of an approximate solution. Much confusion, however, has been obliterated by the hypothesis (first hinted at by Ueberwasser and confirmed by Lewis Campbell and others) that the Sophists and Politicus, whose genuineness had been called in question by Joseph Socher, are really intermediate between the Republic and the Laws. The allocation of these dialogues, not only on grounds of metaphysical criticism, but also on philological and other evidence of a more tangible kind, supplies a point of view from which it becomes possible to trace with confidence the general outlines of Plato's literary and philosophical development. Reflecting at first in various aspects the impressions received from Socrates, he is gradually touched with an inspiration which becomes his own, and which seeks utterance in half-poetical forms. Then first the ethical and by and by the metaphysical interest becomes predominant. And for a while this last is all absorbing, as he confronts the central problems which his own thoughts have raised. But, again, the hard-won acquisitions of this dialectical movement must be fused anew with imagination and applied to life. And in a final effort to use his intellectual wealth for the subvention of human need the great spirit passed away.

It may not be amiss to recapitulate the steps through which the above position respecting the order of the dialogues has become established. Lovers of Hegel had observed that the point reached in the Sophists in defining "not being" was dialectically in advance of the Republic. But Kantian interpreters might obviously have said
the same of the Parmenides: and Grote as a consistent utilitarian looked upon the Protagoras as the most mature production of Plato's genius. It seemed desirable to find some criterion that was not bound up with philosophical points of view. Dr Thompson, the Master of Trinity College, Cambridge, had vindicated the genuineness of the Sophistes against the objections of Socher, but had not accounted for the peculiarities of language, which that acute critic had perceived. By comparing those peculiarities with the style of the Laws, Plato's latest work, and with that of the Timaeus and Critias, which presupposed the Republic, Lewis Campbell argued in 1867 that the Sophistes and Politicus, with the Philebus, were in chronological sequence intermediate between the Republic and the Laws. Thus a further defence of their authenticity was at the same time a long step towards the solution of the problem which Schleiermacher had proposed. Many years afterwards the more detailed stylistic investigations of W. Dittenberger, Constantin Ritter and others arrived independently at the same conclusion. It was vehemently supported by W. Lutoslawski in his work on Plato's Logic, and has been frankly accepted with ample acknowledgments by the high authority of Dr Theodor Gomperz (see especially the Notes to his Greek Thinkers, ill. 310, 315 of English translation).

**The Works of Plato**

The Platonic dialogues are not merely the embodiment of the mind of Socrates and of the reflections of Plato. They are the portraiture of the highest intellectual life of Hellas in the time of Plato—a life but distantly related to military and political events, and scarcely interrupted by them. Athens appears as the centre of the excitable Hellenic mind, profoundly stirred by the arrival of great sophists, and keenly alive to the questions of Socrates, although in the pages of Plato, even more than in reality, he only "whispers with a few strilings in a corner." For, in the Platonic grouping, the agora, which was the chief scene of action for the real Socrates, retires into the background, and he is principally seen consortling with his chosen companions, who are also friends of Plato, and with the acquaintances whom he makes through them. The scene is narrowed (for the Academy was remote from the bustling of resort, and Plato judged the Hellenic world securely from the vantage-ground of partial retirement)—but the figures are distinct and full of life. In reading the dialogues we not only breathe the most refined intellectual atmosphere, but are also present witnesses of the urbanity, the freedom, the playfulness, the generous warmth of the "best society" in Athens. For Plato has a numerous repertory of dramatis personae, who stand in various relations to his chief character—the impetuous Chaerephon, Apollonius the inseparable weak brother, old Crito the true-hearted, Phaedo the beloved disciple, Simmias and Cebes, who have been with Philolaus, the graceful and ingenuous Phaedrus, the petulant Philebus, Theaetetus of the philosophical nature, who is cut off in his prime, and the incorrigible Alcibiades; then Plato's own kinsmen—Glaucus the irrepressible in politics, in quarrel and in love; Adeimantus, solid and grave; Critias in his phase of amateur philosopher, and not as what we call "the old man"; Charmides, Plato's early pupil, but in his first bloom of diificent youth; and many others who appear as mere acquaintances, but have an interest of their own—the accomplished Agathon, the gay Aristophanes, Erxmachus the all-worthy physician; Meno, light of spirit; Callias, entertainer of sophists; Callicles the wilful man of the world; Cephalus the aged father of Lysias; and Nicias the honoured soldier. All these appear, not as some of them do on the page of history, in sanguinary contention or fierce rivalry, but as peaceful Athenians, in momentary contact with Socrates, whose electric touch now benumbs and now exhilarates, and sometimes goads to frenzy of love or anger. Still more distantly related to him, as it were standing in an outer circle, are the impious Gorgias and Protagoras, surrounded with the lesser lights of Hippias, Propodis and Polus. Thrasymachus, Euthydemus, Dionysodorus hang round like comic masks, adding piquancy to the design. The adversaries Anytus and Meletus are allowed to appear for a moment, but soon vanish. The older philosophers, though Socrates turned away from them, also make their entrance on the Platonic stage. Parmenides with his magnificent depth is made to converse with the imaginary Socrates, who is still quite young. A stranger from Elea plays an important part in some later dialogues, and Timaeus the Pythagorean is introduced disclosing of the creation of the world. In these dialogues Socrates is mostly silent; in the Philebus he has lost himself in Plato; and in the twelve books of the Laws, where an unnamed Athenian is the chief speaker, even the Platonic Socrates finally disappears.

Now, in evolving his philosophy from the Socratic basis, Plato works along three main lines—the ethical and political, the metaphysical or scientific, and the mystical. All three are often intimately blended, as in the close of Rep., bk. vi., and even where one element is uppermost the others are not wholly suppressed. But this distinction, like that sometimes made in modern philosophy between the good, the true and the beautiful, is one which, if not unduly pressed, may be usefully borne in mind.

Having noted this once for all, we pass to the more detailed consideration of the several dialogues.

I. **Laches, Charmides, Lysis.**—In this first group Socrates is dealing tentatively with single ethical notions. The result in each case is a confession of ignorance, but the subject has been so handled as to point the way to more fruitful discussions in the future. And suggestions are casually thrown out which anticipate some of the most far-reaching of Plato's subsequent contemplations.

The **Laches** is a vigorous sketch, in which the characters of the soldier, the aged citizen, and the prudent general are well preserved; and Socrates is seen conversing with his elders, although with reference to the treatment of the young. The question raised is the definition of courage; and the humour of the piece consists in showing that three men, all of whom are unquestionably brave, are unable to give an account of bravery, or to decide whether courage is an animal instinct or a mental accomplishment.

Similarly, in the dialogue which bears his name, the temperate Charmides, of whom all testify that (as Aristophanes has it), 'he fills up the gracious mould of modesty,' is hopelessly embarrassed when challenged by the Socratic method. They put words into the mouth of this model of temperance which he possesses, and which, as Socrates assures him, is a priceless gift. The **Charmides** contains some hints of Platonic notions, such as that of knowledge as self-consciousness, and of virtue as "doing one's own business."

The graceful little dialogue which bears the name of Lysis ends, like the two former, with a confession of failure. Socrates, Lysias and Menexenus are all friends, and think highly of friendship, yet after many efforts they are unable to tell "what friendship is." Yet some of the suggestions which are here laid aside are afterwards allowed to reappear. The notion that "what is neither good nor evil loves the good because of the presence of evil" is expanded and emphasized in the Symposium, The friendship then becomes an axis of the Symposium, and the conception of an ideal object of friendship, an ανδρὸν φιλόν (though rejected as in the criticism of Aristotle by the characteristic redolio ad infinitum), is destined to have a wider scope in the history of Platonism.

II. **Protagoras, Io, Meno.**—The previous dialogues have marked the distinction between unconscious and conscious morality, and have also brought out the Socratic tendency to identify virtue with the knowledge of good. Now, the more strongly it is felt that knowledge is inseparable from virtue the more strange and doubtful appears such unconscious excellence as that of Laches, Charmides or Lysis. Hence arises the further paradox of the case: "Virtue is not taught, and that which is taught is not virtue at all." This is a maxim regarded as virtue springs up spontaneously or is received unconsciously by a kind of inspiration. **Protagoras**, in the dialogue named after him, is the professor of popular, unscientific, self-complacent excellence; while

---

1 Nab., 995, τὴν ἀπόταξιν μᾶλλον τἀγαλη ἀπαθικῇ.
Socrates appears in his life-long search after the ideal knowledge of the best. The two men are naturally at cross purposes.

*Protagoras.*

Protagoras contends that virtue is taught by himself and others more or less successfully, and is not one but many. Socrates disputes the possibility of teaching virtue (since all men equally profess it, and even statesmen fail to give it to their sons), but insists that, if it can be taught, virtue is not among the so-called "transitory things." The discussion thus now turns on the nature of knowledge, in the sense in which Plato conceives it. But in the course of it Plato vividly sets forth the natural opposition between the empiric and scientific points of view, between a conventional and an intellectual standard. He does full justice to the thesis of Protagoras, and it is not to be supposed that he was contented to remain in the attitude which he has here attributed to Socrates. In his ideal state, where the earlier training of the best citizens is a refinement on the actual Hellenic education, he has to some extent reconciled the conceptions which are here dramatically opposed.

The preparations for the encounter and the description of it include many life-like touches—such as the eagerness of the young Athenian gentleman to hear the sophist, though he would be ashamed to be thought a sophist himself; the confusion into which the house of Callias has been thrown by the crowd of strangers and by the self-importance of rival professors; the graceful dignity of the man who has been forty years a teacher, the graphic description of the whole scene, the characteristic speeches of Prodicus and Hippias (from which some critics have elicitied a theory of their doctrines), and the continued irony with which Socrates bears them all in hand and soothes the great man after discouraging him.

In the argument there are two points which chiefly deserve notice. (1) *Protagoras,* in accordance with his relative view of things (which Plato afterwards criticized in the *Theaetetus*), claims not to teach men principles but to improve them in those virtues which Providence has given to some more than to all civilized men. (2) Socrates in postulating a scientific principle, which he expressly reserves for future consideration, would have it tested by the power of calculating the amount of pleasure. Grote dwells with some complacency on the "utilitarianism" of Socrates in the *Protagoras.* And it is true that a principle of utility is here opposed to conventional sentiment. But this opposition is intended to prepare the way for the wider and deeper contrast between an arbitrary and conventional morality and an intellectual morality based on all civil knowledge. And when Plato (in the *Gorgias* and *Philebus*) endeavours to define the art of measurement, which is here anticipated, it is not wonderful that differences here unthought of should come into view. The main point should here be considered, is the contrast from the good. In all three dialogues he is equally asserting the supremacy of reason.

On the first point of that transcendental knowledge 1 which is to be the key at once to truth and good, philosophy is apt to lose her balance, and to look with scorn upon "the trivial round, the common task," and the respectable commonplace of "ordinary things." Socrates in the *Lysis* attributes this to the intervention of an unconscious wisdom also a value. And Plato, who, when most ideal, ever strives to keep touch with experience, is fully convinced of the reality of this lower truth, of this unphilosophical virtue. But he is long puzzled how to conceive of it. For, if knowledge is all in all, what are we to make of wisdom and goodness in those who do not know? Protagoras had boldly spoken of honour and right as a direct gift from Zeus, and Socrates, in the *Io* and *Meno,* is represented as adopting an hypothesis of inspiration in order to account for these unaccustomed graces of the soul.

Socrates has observed that rhapsodists and even poets have no definite knowledge of the things which they so powerfully represent (cf. *Apol.* 22; *Phaed.* 245 A; *Rep.* iii. 308 A). He brings the rhapsode *Io* to admit this, and to conclude that he is the inspired medium of a magnetic influence. The Muse is the chief magnet, and the poet is the first of a series of magnetic rings. Then follow the rhapsode and the actor, who are rings of inferior power, and the last ring is the hearer or speaker of the word.

1 *Meno* raises again the more serious question, Can virtue be taught? Socrates here states explicitly the paradox with which the *Protagoras* ended. "Virtue is knowledge; therefore virtue can be taught. But virtue is not taught. Therefore (in the highest sense) there can be no virtue." And he repeats several of his former reasons—that Athenian statesmen failed to teach their sons, and that the education given by sophists is unsatisfying. (The sophists are here denounced by Anytus, who is angered by Socrates' ironical praise of them.) But the paradox is softened in two ways: (1) the absence of knowledge does not preclude inquiry, and (2) though virtue cannot be taught, yet there is a sense in which virtue exists.

1. *Menon* begins in gaiety of heart to define virtue, but is soon "wide-eyed" by the absurdity of the question. He asks "How can one inquire about that which he does not know?" Socrates meets this "eristic" difficulty with the doctrine of reminiscence (*aiktēmenon*). All knowledge is latent in the mind from birth through kindred (or association of) ideas, or may be recovered, if only a beginning is made. Findar and other poets have said that the soul is immortal and that she has passed through many previous states. 2 And Socrates now gives a practical illustration of the truth that knowledge is evolved from ignorance. He elicits, from a Greek slave of Meno's, the demonstration of a geometrical theorem. 3 About the middle of the process he turns to Meno and observes that the slave (who has made a false start) is now becoming conscious of ignorance. He then gradually draws from the man, by leading questions, the positive proof.

2. Though virtue is not yet defined, it may be affirmed "hypothetically" that, if virtue is knowledge, virtue can be taught. And experience leads us to admit two phases of virtue—those of a mode of life based on scientific principle, which hitherto is an ideal only: the other sporadic, springing of itself, yet of divine origin, which is true virtue. Both are known by the slave to be fast through demonstration of the cause or reason. But if there were a virtuous man who could teach virtue he would stand among his fellows like Teiresias amongst the shades.

3. The mystical account of ordinary morality is in keeping with the semi-mythical defence of the process of inquiry—that all knowledge is implicit in the mind from birth.

III. *Euthyphro, Apologia, Crito, Phaedo.*—There is no ground for supposing that these four dialogues were written consecutively, or that they belong strictly to the same period of Plato's industry. But they are linked together for the reader by their common reference to the trial and death of Socrates; no one of them has been proved to be in the author's earliest or latest manner; and they may therefore fitly end the series of dialogues in which the personal traits of the historic Socrates are most uppermost, and Plato's own peculiar doctrines are as yet but partially disclosed.

The little dialogue known by the name of *Euthyphro* might have been classed with the *Laches, Charmides* and *Lysis,* as dealing inconclusively with a single notion. But, *Euthyphro,* although slight and tentative in form, it has an undertone of deeper significance, in keeping with the gravity of the occasion. Plato implies that Socrates had thought more deeply on the nature of piety than his accusers had, and also that his piety was of a higher mood than that of ordinary religious men.

Euthyphro is a soothsayer, well-disposed to Socrates, but not one of his particular friends. They meet at the door of the king *Archon*, where Socrates has been summoned for the "precon- viction" (*anarkēre*) preliminary to his trial. Both men are interested in cases of alleged impiety. For Euthyphro's business is to impeach his father, who has inadvertently caused the death of a criminal labourer. The prophet feels the duty of purging the stain of blood to be more imperative the nearer home. Socrates is struck by the strong opinion thus evinced respecting the nature of piety and detains Euthyphro at the entrance of the court, that he may prove why an old man who feels too clearly the divine rights against Meletus. He leads his respondent from point to point, until the doubt is raised whether God loves holiness beyond the holy, or is it holy holiness? if so, then one can "torture" both pang and so be fortified against Meletus. He here he finds them themselves wandering round and round. Socrates proves himself an involuntary Daedalus who makes opinions move, when he can't even state the question.

"The holy is a portion of the just." But what portion? "Due service of the gods by prayer and sacrifice." But how does this affect the gods? "It pleases them." Again we are found to be ronding a circle.

"Thus far has Socrates proceeded in placing religion on a moral foundation. He is seeking to realize the harmony of religion and 2 The origin of this traditional belief is very obscure. The Greeks themselves were apt to associate it with Pythagoras and with the *Orphic* mysteries.

3 Hom. *Odyss.* x. 435, Ὀλυσσείς νομίμως, τοι ἑαυτῷ ἐνομίζοντο.

4 Ὀλυσσείς νομίμως, τοι ἑαυτῷ ἐνομίζοντο.
morality, which the great poets Aeschylus, Sophocles and Pindar had unconsciously anticipated, and which is the universal want of all men. To this the soothsayer adds the ceremonial element, "attracting upon the gods." When further interrogated by Socrates as to the nature of this "attention to the gods," he replies that piety is an affair of business, a science of giving and asking and the like. Socrates points out the anthropomorphism of these notions. But he is not satisfied with this. He next goes on to show that the necessary function of the gods is the service of the spirit and co-operation with them in all things true and good, he stops short; this was a lesson which the soothsayer could not have been made to understand, and which even himself had not understood.

In Plato's Apology the fate of Socrates is no longer the subject of mere allusions, such as the rage of Anytus at the end of the Meno, and the scene and occasion of the Euthyphro. He is now seen face to face with his accusers, and with his countrymen who are condemning him to death. What most aggravated his danger (after life-long impunity) is thus stated by James Riddell, in the introduction to his edition of the dialogue: "The προσωπεία ("deem") of the restored people did not last long, and was naturally succeeded by a sensitive and fanatical zeal for their revived political institutions. Inquiry into the foundations of civil society was obviously rather perilous for the inquirer at such a time. Socrates knew the danger, and in conformity to Xenophon (Meno, iv. c. 8, § 14), he prepared no defence, alleging that his whole life had been a preparation for that hour." The tone of the Platonic Apology is in full accordance with that saying; but it is too elaborate a work of art to be taken literally as a report of what was actually said. Jowett well compares it to "those speeches of Thucydides in which he has embodied his conception of the lofty character and policy of the great Pericles." Yet it is significant that Plato is said to have been present at the defence, as he is also said to have been absent at the last scene of the Phaedo. Some of the topics may have been actually used by Socrates, and the recollection of his very words may have rung in the ears of the people.

The Platonic Apology is in three parts: (1) before conviction, (2) after conviction and before sentence, (3) after the sentence.

1. Socrates cares not for acquittal. But he does care to explain his life. And he selects those aspects of it which there is hope of making his audience understand. That he partly succeeded in this is shown by the large number of those (220 out of 500) who voted for his acquittal.

a. His answer to Meletus, as least important, is reserved for the middle. He addresses himself first to "other accusers"—comics poets and the rest, who have prejudiced his reputation by falsely identifying him with the physical philosophers and the scoffers. But what is the strange pursuit which has given to Socrates "the title of a comic poet"? He has nothing in common with the comic poets, to whom he was first impelled by the oracle at Delphi, and which he has followed ever since as a religious mission. The god said "to him of old that he was the wisest of all men; but why is no word has been said about this. So he went in search of some one wiser than himself, but could find none, though he found many who had conceit of wisdom. And he inferred that the god must mean "he is wisest who, like Socrates, is most aware of his own ignorance." This unceasing quest has left him in great poverty, and has made him enemies, who are represented by Anytus, Meletus and Lycon. And their enmity is further embittered by the pleasure which young men take in seeing pretence unmasked, and in imitating the true service of reputation. Hence has arisen the false charge that Socrates is a corrupter of youth.

b. Here he turns to Meletus. "If I corrupt the youth, who does think so of me?" "The laws, the judges, the audience, the Athenians generally." (cf. Protagoras and Meno). "Strange, that here only should be one to corrupt and many to improve; or that any one should be so infatuated as to wish to injure his neighbours." Mel. "Socrates is an atheist. He believes the sun to be a stone." "You are accusing Anaxagoras. I have said that I knew nothing of such theories. And you accuse me of introducing novel notions about divinities. Are you more than I believe are the swindlers in divinities ( λυκοπληκτοι) and how in divine beings, if not in gods who are their authors?"

c. That is a sufficient answer for his present accuser. He returns to the general-long-standing defamation, which says that his death is slander has often been and will again be the death of many a man. Yet if spared he will continue the same course of life, in spite of the danger. The Meletus and Demosthenes, who he faced death where the Athenians posted him, so now he will remain at the post where he is stationed by the god. For to fear death is to assume pretended knowledge.

One thing is certain. A worse man cannot harm a better. But in any case where Socrates was to be condemned, he will not say, "This is the will of the gods." For they will lose the stimulus of his exhortations—and his poverty is a sufficient witness that he was sincere. Not that he would engage in politics. If he had done that he would have perished long before. For Platonists, in order to be independent of the battle of Arginusae, and for disobeying the murderous command of the Thirty Tyrants.

But have not Socrates's disciples, Alcibiades, Critias, Charmides, proved him false to the citizens? He has no disciples. Any one, bad or good, may come and hear him, and the talk which is his life-work is not unamusing. But why are no witnesses brought to substantiate this claim? There is no witness who would be angry if he had used his influence for harm. But these men's confidence in Socrates is unshaken.

He will not appeal ad misericordiam. That would be a disgrace for an Athenian (rightly or not) has been required wise, and to admit such an appeal in any case is a violation of the juror's oath.

Socrates has told the Athenians the whole truth, so far as a mixed audience of them could receive it. Elaboration and subtility of thought have never prevailed in the Holistic court; nor could that universal truth towards which he was leading men be made intelligible to a new audience while the cephæydra was running. But his tone and attitude must have made a strong appeal to the better nature of his hearers. With Meletus he "played rather than fought," but he has shown clearly that he has no fear of death, that he chooses to obey God rather than man, and that for very love of the Athenians he is the swayer.

2. One convicted on a capital charge had the right of pleading before sentence in mitigation of the penalty proposed by his accuser. Socrates was convicted by fewer votes than he himself anticipated. The impression which the use of the speeches had not been for the speeches of Anytus and Lycon the defendant would have been triumphantly acquitted. Could he but have conversed with his judges more than once, he might have removed their prejudices. In no spirit of bravado, therefore, but in simple justice to himself, he meets the claim of Meletus that he shall be punished with death by the counterclaim that he shall be maintained in the pyraneum as a public benefactor. He cannot ask that which may be a good, shall be committed for imprisonment or exile, which are certainly evils. A fine would be no evil; but he has no money—he can offer a mina. Here Plato and other interpreters, and writers more recent, have disagree with him. He is sentenced to death, and the public business of the court is ended. But while the record is being entered and the magistrates are thus occupied, Socrates is imagined as addressing (a) the multitude, and (b) the minority in the court.

a. To those who have condemned him he speaks in a prophetic tone. "For the sake of depriving an old man of the last dregs of life they have given Athens a bad name. He would not run away, and Athens has lost him, but his accusers are overtaken by unrighteousness, and must reap the fruits of it."

b. "Nor will the Athenians find the desired relief. Other reprovers, whom Socrates has hitherto restrained, will now arise, in a time when a wise and great man has been brought to death. This indicates that death is not an evil. And reason shows that death is either a long untroubled sleep, or removal to a better world, where there are no unjust judges."

c. "No evil can happen to a good man either in life or after death. Wherefore Socrates will not be angry with his condemners, who have done him no harm, although they meant him anything but good. He will only ask them to do to the sons of Socrates as Socrates has done to them."

Is the love of truth consistent with civic duties? Is the philosopher a good citizen? are questions which are sure to arise where the truth involves practical improvement. Crito. In the Apology Socrates appears as an intrepid reformer; the Crito gives an impressive picture of him as a loyal and law-abiding Athenian.

Execution had been delayed during the annual mission to Delos (during which no one could be put to death). But the returning vessel was advised to put the death sentence into execution. At evening Crito, the oldest friend of Socrates, obtained access to his cell, and found him sleeping peacefully. Presently he awoke, and Crito told him of the approach of the fatal ship. Socrates replies by telling him to return home.

"The third day hence to Phthia shalt thou come" And it would seem that the day after to-morrow will really be the day for going home.}
Crito then reveals his plan for an escape. And Socrates argues the question in the old familiar way. "Crito's zeal is excellent, and most men would think his object right. But the few who think soundly say that it is wrong to return evil for evil. The law, as it stands, is the fault of the whole society. But ought he therefore to infringe the law? Might not the laws of his country plead with him and say: 'You owe to us your birth and breeding; and when grown up you voluntarily submitted to us. Might we therefore go, without your consent, to all other laws, and have been the most constant resident in Athens. Even at the last you accepted death rather than exile. If now you break your covenant, you will ruin your friends and will be rejected by all well-ordered cities. You might be received in Thessaly, but could only live there by cringing to foreigners for food. Where in that case will be your talk about virtue? you would see virtue in being a friend to the rest of the world, and equally kind to them if you were dead. Think not of life and children first and of justice afterwards, but think of justice first, that you may be justified in the world below." 

Crito admits these arguments to be unanswerable.

The *Meno* referred to the immortality and pre-existence of the soul as a traditional doctrine, and it was there associated with the possibility of inquiry. In the *Phaedo* Plato undertakes to substantiate this belief and base it anew by narrating the last hours of Socrates, who is represented as calmly discussing the question with his friends when his own death was immediately at hand. The argument turns chiefly on the eternity of knowledge, and is far from satisfying. For, granting that eternity of knowledge involves eternity of mind, does the eternity of mind assure continued being to the individual? Yet no unprejudiced reader of the *Phaedo* can doubt that Plato, at the time of writing it, sincerely believed in a conscious personal existence after death. The words of Socrates, when he declares his hope of going to be with other friends, are absolutely unambiguous, and his reply to Crito's question, "How shall we bury you?" has a convincing force beyond all dialectic: "I cannot persuade Crito that I here am Socrates—I am now reasoning and ordering discourse. He imagines Socrates to be that other, whom he will see by and by, a corpse." This and similar touches not only stamp the *Phaedo* as a marvellous art, but are indisputable evidence of the writer's profound belief. They may be inventions, but they have nothing "mythical" about them, any more than the charge of Socrates to his friends, that they would best fulfill his wishes by attending to their own lives. 

The narrative, to be appreciated, must be read in full. But a short abstract of the argument may be given here. Socrates, with Socrates and the soul. And this is the very consummation at which philosophy aims. The body harbours the soul. The mind attains to truth by retiring into itself. Through no bodily sense does she perceive justice, beauty, goodness, truth, and perfection, but the soul in the soul. The philosopher has a life-long quarrel with bodily desires, and he should welcome the release of his soul. Thus he alone can have true courage, even as temerity and all the virtues are real in him alone. 

But does the soul exist after death? a. An old tradition tells of many successive births, the soul departing to Hades and returning again, so that the living are born from the dead. And if the dead had not been, some from nothing nothing can arise. Moreover, experience shows that opposite states come from their opposites, and that such a process is always reciprocal. Death certainly succeeds to life. Life must succeed to death. We thus see that what has undergone these changes must exist through all. If the dead came from the living, and not from the living from the dead, the universe would ultimately be consumed in death.

This presumption is confirmed by the doctrine (here attributed to Socrates, cf. *Meno*) that knowledge comes from recollection. What is recollected must be previously known. Now we have never since had intuition of the absolute equality of which (through the eye of the soul) we stand. The philosopher has a life-long quarrel with bodily desires, and he should welcome the release of his soul. Thus he alone can have true courage, even as temerity and all the virtues are real in him alone. 

b. To charm away the fears of the "child within," Socrates adds, as further considerations:—

1. In the *Timaeus* immortality is made to rest on the goodwill of God, because "only an evil being would wish to dissolve that which is harmonious and happy" (Tim. 41 A).

The soul is uncompounded, incorporeal, invisible, and therefore indissoluble and immutabl. 

i. The soul commands the body; serves; therefore the soul is akin to the divine. 

ii.有人说the body holds together long after death, and the bones are all but indestructible. 

The soul, if pure, departs to the invisible world, but, if tainted by communion with the body, she lingers hovering near the earth, and there is no excessive virtue. "The soul of a man," says Socrates, "which true philosophy has purified alone rises ultimately to the gods. The lesson is impressively applied." 

b. A pause ensues; and Simmias and Cebes are invited to express their doubts. For, as the swan dies singing, Socrates died disconsoling.

a. Simmias desires not to rest short of demonstration, though he is willing to make the highest attainable probability the guide of life. 

If the soul is the harmony of the body, what becomes of her "when the lute is broken"? 

b. Cebes has raised the wide question whether the soul is independent of generation and corruption. Socrates owns that he himself (i.e. Plato) had once been fascinated by natural philosophy, and had sought to show that "all being is one." Then, hearing out of Anaxagoras that mind was the disposer of all, he had hoped to learn not only how things were, but why. But he found Anaxagoras to be "an agreeable and jumbling causes with conditions. (The cause why Socrates sits here is not a certain disposition of joints and sinews, but that he has thought best to undergo his sentence—else the joints and sinews would have ere this, by Crito's advice, on the way to Thessaly.)" Physical science never thinks of a power which orders everything for good, but expects to find another Atlas to sustain the world more strong and lasting than the reason of the best. 

Socrates had talked of the soul. He would be found for himself a way, not to gaze directly on the universal reason, but to seek an image of it in the world of mind, wherein are reflected the ideas, as, for example, the idea of beauty, through partaking of the nature of beauty. Socrates, the sole proprietor of the existence of the ideas, he felt his way from hypothesis to hypothesis. 

Now the participation of objects in ideas is in some cases essential and inseparable. Snow is essentially cold, fire hot, three odd, two even. And things thus essentially opposite are inclusive of each other's attributes. (When it was said above that opposites come from opposites, not opposite things were meant, but opposite states or conditions of one thing). Snow cannot admit heat, nor fire cold; for they are inseparable vehicles of heat and cold respectively. The soul is the inseparable vehicle of life, and therefore, by parity of reasoning, the soul cannot admit of death, but is immortal and indestructible. 

3. What follows is in the true sense mythological, and is admitted by Socrates to be uncertain: "Howbeit, since the soul is proved to be immortal, men ought to charm their spirits with such tales." The earth, a globe well-balanced in the middle of space, has many mansions for the soul, some higher and brighter, some lower and darker than our present habitation. We who dwell about the Mediterranean Sea are like frogs at the bottom of a pool. In some higher plane, under the true heaven, our soul's desire of form can be fulfilled, and see not only colours and forms in their ideal purity but truth and justice as well. 

In the *Phaedo*, more than elsewhere, Plato preaches withdrawal from the world. The Delian solemnity is to Socrates...
and his friends a period of "recess," in which their eyes are turned from earthly things to dwell on the eternal. The theory of ideas here assumes its most transcendental aspect, and it is from portions of this dialogue and of the Phaedrus and Timaeus that the popular conception of Platonism has been principally derived. But to understand Plato rightly it is not enough to study isolated passages which happen to charm the imagination; nor should single expressions be interpreted without regard to the manner in which he presents the truth elsewhere.

It has already been shown (1) that Socratic inquiry implied a standard of truth and good, undiscovered but endlessly discoverable, and to be approached inductively; and (2) that in Plato this implicit assumption becomes explicit, in the identification of virtue with knowledge (Lach., Charm.), as an art of measurement (Protag.), and in the vision (towards the end of the Lysis) of an absolute object of desire. The Socratic "self-knowledge" has been developed (Charm.) into a science of mind or consciousness, apart from which no physical studies can be fruitful. (3) Co-ordinate with these theoretical tendencies there has appeared in Plato the determination not to break with experience. In the Phaedo, a long step is made in the direction of pure idealism. The ordinary virtue, which in the Protagoras and Meno was questioned but not condemned, is here rejected as unreal, and the task proposed to the philosopher is less to understand the world than to escape from it. The universal has assumed the form of the ideal, which is supposed, as elsewhere in Plato, to include mathematical as well as moral notions. The only function of perception is to awaken in us some reminiscence of this ideal. By following the clue thus given, and by searching for clearer images of truth in the world of mind, we may hope to be emancipated from sensation, and to lay hold upon the sole object of pure reason.

It is obvious that when he wrote the Phaedo Plato conceived of universals as objective entities rather than as forms of thought. The notion of "ideal colours" (though occurring in the myth) is an indication of his ontological mood. Yet even here the ἐνθέο are not consistently hypostatized. The notion of "what is best" has a distinctly practical side, and the "knowledge through reminiscence" is in one aspect a process of reflection on experience, turning on the laws of association.1 It is also said that objects "partake" of the ideas, and some concrete natures are regarded as embodiments or vehicles of some of them. Still if knowledge is not as a whole, notwithstanding the scientific attitude of Socrates, the Phaedo is rather a meditation than an inquiry—a study of the soul as self-existent, and of the mind and truth as coeternal.

IV. Symposium, Phaedrus, Cratylus.—Socrates is again imagined as in the fullness of life. But the real Socrates is becoming more and more inextricably blended with Platonic thought and fancy. In the Apology there is a distinct echo of the voice of Socrates; the Phaedo gives many personal traits of him; but the dialogues which are now to follow are replete with original invention, based in part, no doubt, on personal recollections. The Symposium admits both of comparison and of contrast with the Phaedo, with both mystical and spiritual, but the spirituality in either is of a different order. That is here immanent which was there transcendent; the beautiful takes the place of the good. The world is not now to be annihilated, but rather transfigured, until particular objects are lost in universal light. Instead of flying from the region of growth and decay, the mind, through intercourse with beauty, is now the active cause of production. Yet the life of contemplation is still the highest life, and philosophy the true house.

The leading conception of the Symposium has been anticipated in the Lysis, where it was said that "the indifferent loves the good, because of the presence of evil." The banqueters (including Socrates), who are met to celebrate the tragic victory of Agathon, happen not to be disposed for hard drinking. They send away the flutegirl and entertain each other with the praise of Love. Phaedrus tells how Love inspires to honourable deeds, and how Alcestis and Achilles died for Love. Pausanias rhythmically distinguishes the earthly from the heavenly Love. The physician Eryximachus, admitting the distinction, yet holds that Love is the same in all places, and that following the higher Love in each particular sphere. So Empedocles had spoken of Love as overcoming previous discord. For opposites the idea of the Heraclitean and Pythagorean myth, describes the origin of Love as an imperfect creature's longing for completion. The original double human beings were growing impious, and Zeus split them in twain, ever since which act the heavenly halves wander in search of harmony. Agathon or rather sings, of Love and his works. He is the youngest, not the eldest of gods, living and moving delicately wherever bloom is and in the hearts of men—the author of all virtue and of all good works—most praised by gods and men alike. And as to be of one mind at feasts—pilot, defender, saviour, in whose footsteps all should follow, chanting strains of love.

Socrates will not attempt to rival the poet, and begins by stipulation that he may avoid pursuing the distinction between Love and his works, but points out that, since desire implies want, and the desire of Love is toward beauty, Love, as wanting beautiful things and not beautiful, so much being established in the Socratic manner, he proceeds to unfold the mystery once revealed to him by Diotima, the Mantineaean wise woman. Love is neither beautiful nor ugly, neither wise nor foolish, neither god nor mortal, but rather "half a god and half a man." Other spirits (rēbōũnaivos). And Love is a great spirit, child of Resource (the son of Prudence) and Poverty the beggar maid, who conceived him at the birthday feast of Aphrodite. He is far from living "herebelow" but is an immortal, always brimming with invention, a mighty hunter after wisdom and all things fair; sometimes "all full with feasting" on them, sometimes "all empty, and ashamed" of himself, and not knowing nor quite ignorant. That is to say, he is a "philosopher." For knowledge is the most beautiful thing, and love is of the beautiful.

But what does love desire of the beautiful? The possession is enough. But there is one kind of love—called "being in love"—which desires beauty for a peculiar end. The lover is seeking, not his "other half," but possession of the beautiful and birth in beauty. For there is a sense in which we must beget beauty, even if we were to achieve only a spirit of modesty, which may be the human nature longs to create, and it cannot, save in possession of beauty. This yearning is the earnest of immortality. Even in the bird's devotion to its mate and to its young there is a craving which leads the bird to pursue and encase the object of its love, not only of the body, but in the mind. Nay the sciences themselves also come and go (here the contrast to the Phaedo is at its height). But the ideal things cannot be beautiful. The love of fame is a somewhat brighter image of immortality than the love of offspring. Creative souls would bring into being not children of their body, but good deeds. And such a one is not to fail in love with a fair maiden, for a world of things is filled with enthusiasm and begets noble thoughts. Homer, Hesiod, Lycurgus, Solon, were such genial minds. But they stopped at the threshold (cf. Prot., Meno), and saw not the higher mysteries, which Socrates now reveals, and which rose full-blown into the new world of abstract ideas. They saw no beauty at all, no knowledge of and acquaintance with Being, its relations, laws, to universal beauty. The true order is to advance from one to all fair forms, then to fair practices, fair thoughts, and lastly to the single thought of absolute beauty. In that completeness, which, beholding closely, brings forth realities and becometh the friend of God and be immortal, if mortal man may.

Alcibiades here breaks in and is vociferously welcomed. He is crowning his action, whose perceiving Socrates, he declares that he will crown him too. Then he announces himself king of the feast, and insists upon hard drinking (though this will make no difference to Socrates). Eryximachus demands from the newcomer such praise of love. But Alcibiades will praise no one else when Socrates is near. And with the freedom of one who is deep in wine he proceeds with his strange encomium of "this Marsyas." In a word, he makes him, as it were, by the voice by which he charms more powerfully than they do by their pipings. The eloquence of Pericles has no effect in comparison with his. His words alone move Alcibiades to shame, and fascinate him until he stops his ears and runs from him."2 I often wish him dead. Yet that would break my heart. He brings me to my wit's end."2

And, as carved Sileni are made to encase images of gods, so this Silenus-mask enheartens things divine. He affects ignorance and is wise; he makes nothing for outward shows, and his temperance (ωρθοποιία) is wonderful." To prove this Alcibiades reveals his own heart-secret. (He is not ashamed to speak it among friends.) The way in which the Socrates以内, and he makes it abundantly manifest that in their widely rumoured intercourse (cf. Protag., init.) Socrates had never cared for anything but what was best for his younger friend. And all this, as we shall see, is made plain by show at Socrates at Potidaea, his strange persistence in solitary meditation—standing absorbed in thought for a day and a night together—and his intrepid conduct in the retreat from Delium (cf. Laches). "The talk of Socrates is of pack-asses and

1 Cf. Theaet. 184-186.
cobbler, and he is ever saying the same things in the same words; but one who lifts the mask and looks within will find that no other words have meaning." Alcibiades ends by warning his companions against the wiles of Socrates.

Some rality follows, and they are invaded by another band of revellers, who compel them to drink still more deeply. The soberly inclined (led by Eryximachus) slink off, and Aristodemus, the reporter of the scene, only remembers further that when he arose at cock-crow Socrates was still conversing with Agathon and Aristophanes, and showing them that tragedy and comedy were essentially one. He talked them both asleep, and at daybreak went about his usual business.

The philosopher of the Symposium is in the world and yet not of it, apparently yielding but really overcoming. In the Phaedrus the soul was exulted to "live upon her servant's loss," as in Shakespeare's most religious sonnet; this dialogue tells of a "soul within sense" in the spirit of some more recent poetry. By force of imagination rather than of reason, the reconciliation of becoming (\(\gamma\iota\rho\epsilon\sigma\sigma\omega\) with being (\(\gamma\iota\omicron\Alpha\omicron\)) of the temporal with the eternal, is anticipated. But through the bright haze of fancy and behind the mask of irony, Socrates still appears the same strong, pure, upright and beneficent human being as in the Apology, Cratylus and Phaedo.

The impassioned contemplation of the beautiful is again imagined as the beginning of philosophy. But the "limitless" beauty of the lover is not to be "conquered" by "mundane" forms, beheld by embodied souls, and remembered here on earth through enthusiasm, proceeding by dialectic from multiform impressions to one rational conception, and distinguishing the "lines and veins" of truth. The Phaedrus records Plato's highest "hour of insight," when he willed the various tasks hereafter to be fulfilled. In it he soars to a pitch of contemplation from whence he takes a comprehensive and keen-eyed survey of the country to be explored, marking off the blind alleys and paths that lead astray, laying down the main roads and chief branches, and taking note of the erroneous wanderings of others. Reversing the vulgar adage, he files that he was a hunter of souls.

The transcendent aspiration of the Phaedrus and the mystic glow of the Symposium are here combined with the notion of a scientific process. No longer asking, as in the Protagoras, Is virtue one or many? Plato rises to the conception of a scientific one and many, to be contemplated through dialectic—not barren abstraction, but a method of classification according to nature. This method is to be applied especially to psychology, not merely with a speculative, but also with a practical aim. For the "birth in beauty" of the Symposium is here developed into an art of education, of which the true rhetoric is but the means, and true statesmanship an accidental outcome.

The art of rhetoric, Plato goes to some extent under the influence of that which he criticizes. The art of rhetoric which he so often travestied had a lasting effect upon his style. Readers of his latest works are often reminded of the mock grandiloquence of the Phaedrus. But in this dialogue the poetical side of his genius is at the height. Not only can he express or imitate anything, and produce any effect at will, but he is standing behind his creation and disposing it with the most perfect mastery, preserving unity amidst profuse variety, and giving harmony to a wildness bordering on the grotesque.

The person of Socrates is here deliberately modified. He no longer (as in the Symposium) teaches positive wisdom under the pretence of repeating what he has heard, but is himself caught by an exceptional inspiration, which is accounted for by the unusual circumstance of his finding himself in the country and alone with Phaedrus. He has been hithero a stranger to the woods and fields, which would tempt him away from studying himself through intercourse with men. But by the promise of discourse—especially of talk with Phaedrus—he may be drawn anywhither.

Phaedrus has been charmed by a discourse of Lyasias, which after some coy excuses he consents to read.

The art of writing is kindled to the art of speech. But Socrates maintains that oral teaching through the living contact of mind with mind has many advantages over written composition, which is, comparatively speaking, a dead thing. Men may write for amusements or to render the thought or representation clear to others, but serious occupation of the true thinker and teacher is the communication of truth through vital converse with others like-minded in the creation of "thoughts that breathe" in spirits conscious of the whole.

In conclusion, a friendly hint is given to Isocrates that he may do better than Lysias if he will but turn his attention to philosophy. The Phaedrus anticipates much that Plato afterwards slowly elaborated, and retains some things which he at last eliminated. (1) The presence of the soul in the body is an aspect of truth which reappears in the Sophists and other later dialogues. It has been thought strange that it should be found so early as in the Phaedrus. But does not this remark imply an unwarrantable assumption, viz. that Plato's idealism took its departure from the being of Parmenides? Is it not rather the fact that his own theory was formulated before the Megarian ascendency led him to examine the Eleatic doctrine, and that it was by a tendency from the first inherent in Platonism that that doctrine was modified in its final teaching? (2) The
outlines of method which are thrown out at white heat in the 
Phaedrus are a preparation for the more sober treatment of 
the subject in the dialectical dialogues. In these, however, the 
conceptualism of the Phaedrus is altered through contact 
with Eleaticism. (3) The Phaedrus aims, not merely at realizing 
universals, but at grasping them in and through particulars. 
This is an ideal of knowledge which was "lost as soon as seen," 
but one which in some of his latest dialogues, such as the Politicus 
and Philebus, Plato again endeavoured to work out. (4) The 
Phaedrus contains the elements of that true psychology into 
which the ontological theory of the ideas is gradually transmuted 
in Plato's more advanced writings, when the difficulties of his 
ideal doctrine in its cruder forms have been clearly felt and under-
stood. (5) Plato here appears as a professor of education 
preaching an oral interlude to authorship. In this paradox he 
at once exalts the work of Socrates and avows his own vocation as 
teachers. The passage throws an interesting light upon the form 
of dialogue in which his works are cast. But it is not to be sup-
pposed that he remained long unconscious of the influence he was 
destined to wield by writing. In executing a great task like the 
Republic, he practically diverged from the untenable view 
asserted here; and in the Laws he recommends his longest and 
least dramatic work as a suitable basis for the education of the 
future. (6) It must always appear strange, even to those most 
familiar with the conditions of Hellenic life, that in portraying 
the idealizing power of passionate love Plato should have taken 
his departure from unnatural feelings.

On this subject he has sung his own "palinode" in the Laws, 
which he intended as his final legacy to mankind. Not that he 
ceded to exalt genius and originality above mere talent, or to 
demand for philosophy the service of the heart as well as the head 
nor yet that friendship was less valued by him in later years. 
All this remained unchanged. And in the Republic the passion 
of love is still distinctly referred to as the symbol of ideal aspira-
tion. But a time came when he had learned to frown on the 
aberration of feeling which in the Symposium and Phaedrus he 
appears to regard as the legitimate stimulus of intellectual 
enthusiasm. And already in the Theaetetus not love but wonder 
is described as the only beginning of philosophy.

While calling attention to this change of sentiment, it is right 
to add that Platonic love in the "erotic" dialogues of Plato is 
very different from what has often been so named, and that 
nothing even in the noble passage of the Laws above referred to 
casts the slightest shadow of blame on the Socrates of the 
Symposium. Such changes are, amongst other things, a ground 
for caution in comparing the two steeds of the Phaedrus with the spirit (theos) and desire (erôdia) of the Republic and 
Timaeus. The Phaedrus, in common with these dialogues, 
asserts the existence of higher and lower impulses in human 
nature, but there is no sufficient ground for supposing that when 
Plato wrote the Phaedrus he would have defined them precisely 
as they are defined in the Republic.

The Cratylus is full of curious interest as marking the highest 
point reached by the "science of language" in antiquity; but, 
Cratylus, as this dialogue "hardly derives any light from 
Plato's other writings,"2 so neither does it reflect 
much light on them. It deals slightly with the contrast between 
Heracliteanism and Eleaticism, the importance of dialectic, the 
difficulty about the existence of falsehood, and ends with a brief 
allusion to the doctrine of ideas—but these topics are all more 
fully discussed elsewhere.

Three persons maintain different views respecting the nature and 
origin of language. Hermogenes affirms that language is conventional, Cratylus (the 
Heraclitean) that it is natural. Socrates, mediating between these 
stands, declares that language, or perhaps the "language," is rational, and therefore (1) is based on nature, but (2) modified by 
convention. In his dialectical treatment of the subject, Socrates displays 
a talent of witticism in reliance on the "inspiration" of 
Euthyphro. Presently a distinction appears between primary and 
secondary words. Many primary words convey the notion of 
permanent and change; it follows then the legislator or word-maker 
held Heraclitean views. Socrates thus far prefaces on Hermogenes 
the view of Cratylus. Then turning to Cratylus he asks if there are 
false names. "False language," Cratylus argues, "is impossible." 
Socrates shows that the word-maker must be right, so that we 
have a right to criticize the work of the word-maker. And the facts 
indicate an element of meaningless convention. Nor was the 
original word-maker consistently Heraclitean. For some important 
words point not to motion but to rest.

But the question returns—Are we sure that the theory of nature 
which the word-maker held was true? This difficulty cannot 
be touched by verbal arguments. In seeking to resolve it we must 
consider, not words, but things. If things are a true beauty and a 
true good, which are immutable, and if these are accessible to 
knowledge, that world of truth can have nothing to do with flux 
and becomes change.

V. Gorgias, Republic.—In the Symposium and Phaedrus 
Plato largely redeems the promise implied in the Phaedo, where 
Socrates tells his friends to look among themselves for a cherisher 
who may soothe away the fear of death. But he was pledged also 
(a) to a stern duty by the warning of Socrates to the Athenians, 
in the Apology, that after he was gone there would arise 
others for their reproof more harsh than he had been. To this 
graver task, which he had but partially fulfilled with the light 
savine upon Lysias or the gentle message to Isocrates, the philo-
sopher now directs his powers, by holding up the mirror of what 
ought to be against what is, the principles of truth and right 
against the practice of men. For the good has more than one 
aspect. The beautiful is not always good. The good is not 
always the beautiful. The good is as much a subject for 
beautification as the beautiful is for an improvement through 
beauty. The good is not always the beautiful. The good is 
also the evil. The good is the evil. The good can be made evil, 
and the evil can be made good.

In the Gorgias the Platonic Socrates appears in direct antagon-
ism with the Athenian world. The shadow of his fate is 
impending. Chaerephon (who is still alive) understands 
him, but to the other interlocutors, Gorgias, Polus, 
Callicles, he appears perversely paradoxical. Yet he 
effectively dominates them all. And to the reader of the dialogue 
this image of "Socrates contra mundum" is hardly less impressive 
than that other image of Socrates confronting death.

1. Gorgias asserts that rhetoric is an art concerned with justice, 
and that persuasion is the secret of power. Here Socrates maintains against Polus the three 
paradoxes:

- a. Socrates, after suggesting some ironical doubts, declares 
   that rhetoric is an art, but a kind of pleasing, or in other 
   words "the counterfeit of a subsection of statesmanship." This 
   oracle definition rouses the interest of Gorgias, and Socrates 
   proceeds with the following "generalization and division":—

<table>
<thead>
<tr>
<th>Management of</th>
</tr>
</thead>
<tbody>
<tr>
<td>Soul.</td>
</tr>
<tr>
<td>Legitim. prudence.</td>
</tr>
</tbody>
</table>

Flattery influences men through pleasure without knowledge. 
And the rhetor is a kind of confectioner, who can with difficulty 
deceived from the sophist. 

b. Rhetoric, then, is not an art. And persuasion is not the 
   secret of power. Here Socrates maintains against Polus the three 
   paradoxes:

- a. Socrates, after suggesting some ironical doubts, declares 
   that rhetoric is an art, but a kind of pleasing, or in other 
   words "the counterfeit of a subsection of statesmanship." This 
   oracle definition rouses the interest of Gorgias, and Socrates 
   proceeds with the following "generalization and division":—

<table>
<thead>
<tr>
<th>Management of</th>
</tr>
</thead>
<tbody>
<tr>
<td>Soul.</td>
</tr>
<tr>
<td>Legitim. prudence.</td>
</tr>
</tbody>
</table>

Flattery influences men through pleasure without knowledge. 
And the rhetor is a kind of confectioner, who can with difficulty 
distinguished from the sophist.

2. Callicles here loses patience and breaks in. He propounds 
   his theory, which is based on the opposition of nature and custom.
There is no natural right but the right of the stronger. And natural nobility is to have strong passions and power to gratify them. The lawful is a word that cowards use, Devised at first to keep them from the sight of men all awe.

Socrates entangles him in an argument in which it is proved that pleasure is different from good, and that there are good and bad pleasures.

Now the question is whether the life of philosophy, or the life which Callicles defends, is conducive to good. And it has been shown that rhetoric is one of a class of pursuits which minister to pleasure without discriminating what is good.

Callicles is led to defend not Themistocles, Cinna, Pericles labour for their country's good? Socrates then renewes his demonstration, proving that if the just man is wronged, the evil lies with the wrongdoer, not with him, and that it was wrong to wrong him, which he especially adds; or avoidance of this greatest evil not rhetoric avoids anything, nor any of the arts which save life (seeing that life may be used well or ill), nor even such an art of politics as Themistocles, Cinna, or Pericles knew, but is itself an evil.

The pursuit of it may well endanger him: but his strength lies in having done no wrong. For in the world to come he can present his soul faultless before her judge. Not the show of justice but the reality will avail him there.

This truth is enforced by an impressive myth. And Callicles is invited to leave the life which relies on rhetoric and to follow Socrates in practising the life of philosophic virtue.

The value of justice has been shown. But what is justice?

Is the life upheld by Socrates sufficiently definite for practical guidance? The views of Callicles have been overborne; but have they been thoroughly examined? Socrates claims to be the only politician. But how can that deserve the name of policy which results in doing nothing?

These and cogitate questions may well have haunted Plato when he planned the Republic, the greatest of his works. For that which lay deepest in him was not mere speculative interest or poetical fervour, but the practical enthusiasm of a reformer.

The Republic of Socrates had fired him with an ideal of wisdom, courage, temperance and righteousness, which under various guises, both abstract and concrete, has appeared and reappeared in the preceding dialogues. But the more vividly he conceived of this ideal life, the more clearly he felt its implication in the present world—that of the restored Athenian democracy. For to a Greek who looks above all others life was nothing without the social environment, and justice, of all virtues, could least be realized apart from a community. Hence it became necessary to imagine a form of society in which the ideal man might find himself at home, a state to which the philosopher might stand in harmonious relationship, no longer as an alien sojourner, but as a native citizen, not standing aloof in lonely contemplation, but acting with the full consent of other men and ruling in the right of wisdom. Plato did not regard his own republic as a barren dream. He believed that sooner or later in the course of time a state essentially resembling his ideal commonwealth would come into being. Still more firmly was he convinced that until then the kind would not attain their highest possible development. To ignore this real aspect of his most serious work is to lose much of a great imagination the Republic falls naturally into five portions. (1) Bk. i. is preliminary, raising the main question about justice. (2) Bks. ii.-iv. contain the outlines of the perfect state, including the education of the “guardians,” and leading up to the definition of justice (a) in the state, and (b) in the individual. (3) Bks. v., vi., vii. (which to some critics present the appearance of an afterthought), are concerned with the original design coming to light and the provisory provisions (1) of communism (for the guardians only), (2) that philosophers shall be kings, (3) of higher education for the rulers (viz. the philosopher-kings). This third provision occupies bks. viii.-ix., which is as a whole the appearance of an outgrowth from bk. v.). (4) Bks. viii. and ix., resuming the general subject from bk. iv., present the reverse of the medal by showing the declension of the state and individual through four stages, until in the life of tyranny is found the image of ideal injustice, as that of justice was found in the life of the perfect state. (5) Bk. x. forms a concluding chapter, in which several of the earlier enactments are reviewed, and the work ends, like the Gorgias, with a vision of judgment.

Thus the main outlines of the scheme are contained in bks. ii., iii., iv., v., vii., vii. And yet bks. v., vi., vii. form the central portion, a sort of inner kernel, and are of the highest significance.

In speculating about the composition of the Republic (as is the fashion of some interpreters) it is important to bear in mind the general character of Plato's writings.

"The conception of unity," says Jowett, "really applies in very different degrees to different kinds of art—to a statue, for example, far more than to any kind of literary composition, and the more so of those of the form of body; the dialogue appear to be a style of composition in which the requirement of unity is most stringent; nor should the idea of unity derived from one sort of art be hastily transferred to another. ... Plato subjects himself to no rule of this sort. Like every great artist he gives unity of form to the different and apparently distracting topics which he brings together. He works freely, and is not to be supposed to have arranged every part of the dialogue before he wrote. "Imaginary" is perhaps the best word, or "imagery" to use, which comprehends the process of his discourse loosely and imperfectly, and which is the warp and which the woof cannot always be determined.

It should be added, that as Dialectic was still a "world not realized," and he was continually conscious of using imperfect methods, he was not solicitous to bind himself to any one method, or to watch carefully over the logical coherence of his work. "Sailing with the wind of his argument," he often takes and veers, changing his method with his subject-matter, much as a poet might adopt a change of rhythm. Absorbed as he is in each new phase of his subject, all that precedes is cancelled for the time. And much of what is to come is deliberately kept out of view, because ideas of high importance are reserved for the place where their introduction will have most effect. Another cause of apparent inconsequence in Plato is what he himself would call the use of hypothesis. He works less deductively and more from masses of generalized experience than Platonists have been ready to admit. And in the Republic he is as much engaged with the criticism of an actual as with the projection of an ideal condition of society. If we knew more of the working of Attic institutions as he observed them, we should often understand him better.

The general considerations should be weighed against the inequalities which have led some critics to suppose that the "first sketch of the state" in bks. ii.-iv. is much earlier than the more exalted views of bks. v.-vii. If in these later books new conditions for choosing the future rulers are allowed to emerge, if in discussing the higher intellectual virtues the simple psychology of bk. iv. is lost sight of (it reappears in the Timaeus), if the "knowledge of the expedient" at first required falls far short of the conception of knowledge afterwards attained, all this is quite in keeping with Plato's manner elsewhere, and may be sufficiently accounted for by artistic and didactic reserve. It can hardly be an altogether fortuitous circumstance that the culminating work, the highest "word" of eternity, the dearth of the declaration that philosophers must be kings and kings philosophers—comes in precisely at the central point of the whole long work.

The great principle of the political supremacy of mind, though thus held back through half the dialogue, really dominates the whole. It may be read between the lines all through, even in the institution of gymnastic and the appraisement of the cardinal

PLATO

819

virtues. It is a genuine development of Socratic thought. And it is this more than any other single feature which gives the Republic a prophetic significance as an attempt towards anticipating the work of future generations."

Other aspects of the great dialogue, the Dorian framework, so inevitable in the reaction from Ionian life, the traces of Pythagoreanism, the attempt to系统的ize the characters of the interlocutors in their bearing on the exposition, have been fully treated by recent writers, and for brevity's sake are here passed over.

There are points, however, which must not be omitted, because they are more intimately related to the general development of Plato's thought. The question raised by Proclus has been raised before and since, whether the proper subject of the Republic is justice or the state. The doubt would be more suggestive if put in a somewhat different form: Is Plato more interested in the state or the individual? and more strongly has he worked out his ideas, and this of them they are inseparable, is an obvious answer. And it is almost a truism to say that political relations were prior to ethical in the mind of a Greek. Yet if in some passages the political analogy reacts on moral, or moral on political, in others the state is spoken of in language borrowed from individual life. And it remains questionable whether the ethics or the politics of the Republic are less complete. On the whole Plato himself seems to have been the last of the Ionians, as being the last to give the old Pythagorean view of the state a modern refinement. Socrates could be more readily stamped on individual lives than on communities of men (see especially Rep. viii. 528 A, ix. 592).

2. The individual is the starting point. The realm of the statesman could look steadily on particulars in the light of universal principles. He recurs often to experience, but is soon carried off again into the abstract region which to him seemed higher and purer. It has been said that Plato flies as well as walks, but this hardly expresses the whole truth, for he flies and walks at the same time, and is in the air and on firm ground in successive instants" (Jowett). Plato's scheme of communism had been suggested to him partly by Dorian institutions and partly by the Pythagorean doctrine of the Pythagorean body. But it is the communistic or democratic general consideration that the state is a higher and more abstract unity than the family. The lower obligation must give way to the higher; the universal must override the particular. But, it may be argued that, while the subordination of music to state discipline, and the importance attached to rhythm and harmony in education, had likewise a connexion with Sparta and the Pythagoreans, severally, Plato's deliberate attitude towards poetry and art could hardly be other than it is. Philosophy, while still engaged in generalization, could not assign to the imagination its proper function. "Aesthetik could not enter into her province in the Republic, in the absence of a proper exposition of the arts in general. Poetry and philosophy had seemed to be melted in a dominant tone, but this was only a fond anticipation. Plato, if man ever did, had felt the siren charm, but he is now embarked on a more severely moral voyage. And all the literature of truth and good is grasped, vibrant fancy must be subdued and silent.

3. In the early education of the guardians a place is found for the unconscious virtue acquired through habit, which the Pythagoreans and Plato's later opponents, the Sophists, had rejected. In the ideal state, however, this lower excellence is no longer a wild plant, springing of itself through some unreasoned grace of inspiration, but cultivated through an education which has been prepared by the subordination of all the arts and sciences with reason. But if Plato were cross-questioned as to the intrinsic value of habits so induced as a preservative for his pupils against temptation, he would have replied, I do not pretend to have removed evil from their path. Enough of evil still surrounds them to test their moral strength. I have but cleared the well-springs of the noxious weeds that have been fatal to so many, in order that they may have time to learn, and be exposed only to such dangers as are inevitable."

4. It is a singular fact, and worth the attention of those who look for system in Plato, that the definition of justice here so laboriously wrought out, viz. the right division of labour between the three classes in the state and between the three corresponding faculties in the individual soul, is nowhere else repeated or applied, although the tripartite division of the soul recurs in the Timaeus, and the doctrine of the idea of good is of great importance to the arguments of the Politicus and the Laws.

6. Before leaving the Republic, it is important to mark the stage which has now been reached by Plato's doctrine of ideas. The fragments of the Republic on this subject are by no means consistent.

a. Towards the end of bk. vi. philosophers are defined as lovers of the whole, who recognize the unity of justice, goodness, beauty, each in itself, as distinguished from the many just or good or beautiful things. The former are said to be objects of knowledge, the latter of opinion, which is intermediate between knowledge and ignorance. Knowledge is of being, ignorance of the non-existent, opinion of that which is and is not.

b. In bk. vi. there is a more elaborate statement, implying a more recondite distinction of "knowledge," "opinion," "merely speculative" and "imagination". These are the four "species" of human knowledge and all existence is a riper conception than "the love of each thing as a whole." Ignorance and nonentity have now disappeared, and the scale is graduated from the most expanson impression of sense to the highest reach of absolute knowledge. And in the highest region there is again a gradation, rising to the form of good, and descending from it to the true forms of all things. In the application of this idea to the theory of knowledge there are still further refinements. The psychological analysis becomes more subtle, and more stress is laid on the connection of ideas.

c. The doctrine reverts to a cruder aspect in bk. x, where we are told of an ideal bed, which is one only and the pattern of all the many actual beds.

d. A yet different phase of idealism presents itself in bk. ix. (sub fin.), in the mention of a "pattern" of the perfect state laid up in heaven which the philosopher is to make his rule of life.

What is said above concerning Plato's mode of composition has some bearing on these inconsistencies of expression. And that the two great divisions of the book are not perfectly separated but not mutually exclusive. But that Plato, in preparing the way for what he had in contemplation, should content himself with provisional and approximative ideal expressions instead of the final and illustration (as in bk. x.) he should go back to a crude or even childish form of his own theory, is equally conceivable and in accordance with his manner elsewhere. Socrates in the Parmenides, for example, is supposed to have considered a series of dialogues, probably intended for a narrower circle of readers, in which Plato grapples directly with the central difficulties of his own theory of knowing and being. It is not necessary to assume that all of these are later than the Republic. The position of the Euthydemus and Parmenides in the order of composition is very uncertain. The Theaetetus has points of affinity with the Republic. The Sophist, Politicus and Philebus are in a later style. But, on account of their cognate subject-matter, these six dialogues may be conveniently classed together in a group by themselves. And the right place for such a group is intermediate between the Republic and the Laws.

7. As the object of definition, the identity of virtue and knowledge, the existence of an absolute good, which would be universally followed if universally known, and of a standard of truth which is implied in the confession of ignorance, were postulates underlying the Socratic process, which in so far made no claim to be a "philosophy without assumptions." These postulates, when once apprehended, drew Plato on to speculate concerning the nature, the object and the method of knowledge. Now, so far as we have hitherto followed him, his speculation has either been associated with ethical inquiry, or has been projected in a poetical and semi-mythical form. In the Phaedrus, however, the vision of Ideas was expressly conjoined with an outline of psychology and the method of the Sophists. And, while the opposition of ideas to phenomena and of knowledge to opinion has been repeatedly assumed, it has also been implied that there is a way between them, and that the truth can only be approached by man through interogation of experience. For it is nowhere supposed that the human inquirer is from the first in a position to deduce facts from ideas. Much rather, the light of the ideas is one which fitfully breaks in upon experience as men struggle towards the universal.

But it is not less true that the metaphysical aspirations from which Socrates had seemed to recall men's thoughts had been reawakened in consequence of the impulse which Socrates

---

1 Groce.
2 See, for example, the admission of luxury and the after-purification through "music," bks. ii., iii.
himself had given. From asking, Is virtue one? Can virtue be taught? Plato passes on to ask, What is unity? What are knowledge and being? From criticizing imperfect modes of teaching virtue, he has begun to speculate about the right and wrong uses of the intellect, and from dramatic portraits of the individual Parmenides, he has arrived at the idea of the theory of Parmenides. He has entered upon the "longer way," and is no longer contented with mere "hypotheses." With this demand for scientific precision his conception of the ideas themselves is modified, and he strives anew to conceive of them in relation to one another, to the mind, and to the world. As the balance of ethical truth was restored by admitting an unconscious (or inspired) conformity to reason, so now a fresh attempt is made on the intellectual side to bridge the gulf between sense and knowledge.

This endeavour involves, not only an expansion of the method of Socrates, but an examination of the earlier philosophies from which Socrates had turned away. Their influence on Plato has been traceable in the preceding dialogues, though, except in the case of Pythagoreanism (Gorg., Phaed., Rep.) it has been mostly indirect and casual. But in these dialectical dialogues he manifests his serious conviction that the contemporary fallacies which formed the chief hindrance to inquiry were deeply rooted in forms of thought created by earlier thinkers, above all by Heraclitus and Parmenides. To the exclusiveness of their first principles as held by their followers Plato attributed the barrenness and impracticable unreality of many discussions, which put shadow-fighting and controversy in the place of real investigation, and led men to think that truth was unattainable. He therefore enters into conversation, as it were, with the great minds of former times, and in the spirit of Socrates compels each of them to yield up his secret, and to acknowledge a supplemental truth. To this effort he may very probably have been stimulated by the dialectical activity of his Socratic friends at Megara, whose logical tastes had drawn them towards Eelastics. But, unlike them, while strengthening his metaphysical theory, he was also led to give to his political speculations a more practical turn.

The Euthydemus is a treatise "De Sophisticis Elenchis" in the form of a farce, and may serve to introduce the five other dialectical dialogues, as the encounter with Thrasymachus marks the serious part of the Repub. Under the mask of mockery there is more of concentrated thought, and also more of bitterness, in this dialogue than in the Protagoras or the Gorgias.

A sample of educational dialectic—in which Socrates draws out of young Cleinias the admissions (1) that a philosophy is needed, (2) that the highest philosophy is a science of kingcraft, which remains for the present undefined—is contrasted with a series of ridiculous sophisms, propounded by Dionysodorus and his brother Euthydemus, in which absolute and relative notions, whether affirmative or negative, object and subject, universal and particular, substance and attribute, action and modality, are capriciously confused. Crito, to whom Socrates narrates the scene, is moved to contempt. But Socrates warns him not on this account to despair of philosophy. In conclusion, Iosocrates, or some one else, who prematurely mixes up philosophy with practical politics, is cautioned against spoiling two good things.

Such puzzles as—How can I learn either what I know or what I do not know? How can things become what they are not? How is falsehood or denial possible?—although treated jocularly here, will be found returning afterwards to trouble the mind's eye.

Plato appears in the same act to have become aware of his affinity with Parmenides, and to have been led to reconsider the Parmenides. Of Parmenides was a more abstract notion than justice, beauty or the good. And the Zenonian method had more pretension to exactness than the Socratic. But it remained barren, because contented to repeat its own first essays in the destructive analysis of experience, without rising to the examination of its own first principles. For this higher criticism, of which he himself also stood in need, Plato looks up from the disciples to the master Parmenides. The appeal to him is put into the mouth of Socrates, as a very young man, who has trained for himself a theory of ideas and would gladly see the Zenonian process applied to the notions of sameness, difference, likeness, unlikeness, unity and being.

Parmenides, whom Plato treats with tender reverence not unmixed with irony, proposes to the youth a series of questions which reveal the crudity of the doctrine of édoù. (1) Are there ideas of trivial things? (2) How do things "partake" of them? (3) Must not idealism proceed in infinitum? (4) If ideas are thoughts, do they and their participants think? (5) If they are patterns, and things resemble them, must there not be a pattern of the resemblance, and so on in infinitum? (6) If absolute, are they thinkable by man?

These difficulties are real, and yet to deny ideas is to destroy philosophy. (As the paradoxical doubts in the Protagoras do not shake the faith of Socrates in the existence of good, so neither does Plato here intend for a moment to derogate from the belief in the existence of the One and the True.)

Parmenides advises Socrates to arm himself for the further pursuit of truth (1) by the higher application and (2) by the extension or elaboration of the method of the Gorgias. Parmenides here applies to abstractions. (2) It is not enough to show the inferences which may be drawn from the admission of an hypothesis, but account must also be taken of the inferences which follow from its negation.

Parmenides exemplifies his suggestion by examining his own first principle in conversation with a youth who, while a contemporary of Socrates, is a namesake of Plato's pupil Aristotle. Not content with the affirmative and negative hypotheses, he pursues either along two lines, according as either term of the proposition is emphasized, and this not only as regards the hypothesis of unity, but as applied to the alternative hypothesis of plurality. The result, as in the Protagoras, is purely destructive, and the dialogue ends abruptly without a word of reply from Socrates.

The second part of the Parmenides may be regarded as an experiment in which Plato "assays to go," in Eelastic armour. Yet the strange web is "shot" with colours of original thought. The mode of conceiving time and becoming, and the vision of nothingness towards the end, may be noted as especially Platonic. These passages may be regarded in the same light as the wise words of Protagoras or the sober truths which occur among the wild fancies of the Gorgias. He should not mislead the interpreter into a search for redundant meanings.

The Zenonian method has been carried out to the utmost in application to the highest subject, and has led the mind into a maze of contradiction. It remains to call in question the method itself, and the notion of absolute identity and difference on which it hinges, and so to lay anew the foundation-stone of thought. Before this can be attempted, however, another set of difficulties have to be met, and another set of philosophers examined. For the current scepticism had undermined the conception of knowledge as well as that of being, and the fame of Heraclitus was hardly second to that of Parmenides. Protagoras appeared in a former dialogue as the champion of ordinary morality; he is now made the exponent of ordinary thinking. His saying "Man the measure" is shown to rest on the unstable basis of the Heraclitean flux. By an elaborate criticism of both theories knowledge is at last separated from the relativity of sense; but the subsequent attempt to distinguish on abstract grounds between true and false opinion, and to define knowledge as true opinion with a reason (cf. Memo), proves ineffectual. Plato still shows traces of Megarian influence. But the disjunctive method of the Parmenides is not resumed. The indirect proofs are so arranged as to exhibit the skill of Socrates in "bringing to the birth" the germ of thought in a richly emotional and pregnant young mind. The attunement is the embodiment of the philosophic nature described in Rep. bk. vi., and has already been trained by Thaetorus of Cyrene in geometry and the other preparatory sciences of

1 Cf. Rep. x. 597.
2 Cf. the younger Socrates of the Politicus. It would be precarious to draw any inference from this minute fact.
Rep. bk. vii. It is in conversation with Theodorus that Socrates impressively contrasts the lives of the lawyer and the philosopher. The dialogue is a great advance in clearness of metaphysical and psychological expression. See for example the passage (184-186) in which the independent function of the mind is asserted, and kinds are shown to be the truth of experience. There is a distinct approach towards a critical and historical method in philosophy, while the perfection of style continues unimpaired, and the person of Socrates is as vividly represented as in any dialogue.

Notwithstanding the persistence of an indirect and negative method, the spirit of this dialogue also is the reverse of sceptical. "Socrates must assume the reality of knowledge or deny himself" (107 A). Perhaps in no metaphysical writing is the balance more firmly held between experience, imagination and reflection. Plato would seem to have made a compact with himself to abstain rigidly from snatching at the golden fruit that has so often eluded his grasp, and to content himself with laboriously "cutting steps" towards the summit that was still unascended.

With Plato, as with other inventive writers, a time seems to have arrived when he desired to connect successive works in a series. Thus in planning the Sophists he linked it to the Theaetetus (which had been written without any such intention), and projected a whole tetralogy of dialectical dialogues, Theaetetus, Sophists, Politicus, Philebus, of which the last piece seems never to have been written. After an interval, of which our only measure is a change of style, the philosopher returns to the great central question of knowledge and being. The obstacle in his path, on which he has often played with light satire, dramatic portraiture and indirect allusion, is now to be made the object of a seriously planned attack. He has made his approaches, and the enemy's fortress is to be forthwith sapped and overthrown. This hostile position is not merely the "Sophistik" which, as some tell us, is an invention of the Germans, and as Plato himself declares is only the reflection or embodiment of the average mind, but the fallacy of fallacies, the prime falsehood (πρῶτος φάσεως) of all contemporary thought. This is nothing else than the crude absoluteness of affirmation and negation which was ridiculed in the Euthydemus, and has been elsewhere mentioned as the first principle of the art of controversy. For dramatic purposes this genre of error is personified, and the word "Sophistik" which so soon become the lèse-majesté of the Platonic school, thus for the first time fixedly acquires the significance which has since clung to the name. That Plato himself would not adhere pedantically to the connotation here implied is shown by the admission, at the opening of the dialogue, that amongst other disguises under which the philosopher walks the earth the sophist is one.

In the Sophists, as in the Parmenides, a new method is introduced, and again by an Eleatic teacher. This method is repeated with improvements in the Politicus, and once more referred to in the Philebus. It bears a strong resemblance to the "synagogue" and "diacritical" of the Phaedrus, but is applied by the "friend from Elea" with a degree of scepticism which Socrates nowhere betrays. And the two methods, although kindred, have probably come through different channels—the classifications of the Phaedrus being Plato's own generalization of the Socratic process, while the dichotomies of the Sophists and Politicus are a caricature of Socrates cast in the Megarian mould. Plato seems to have regarded this method as an implement which might be used with advantage only when the cardinal principles on which it turned had been fully criticized.

1. After various attempts to "catch the sophist," he is defined as the maker of an unreal likeness of truth. Here the difficulty begins. The method of definition implies the existence of the unreal, i.e. the notion of not-being. In our extremity it is necessary to "lay hands on our father Parmenides."

2. The contradictions attendant on the notion of "being," as well as held by Parmenides or his opponents or by the "less exact" thinkers who came after them, are then examined, and in an extremely subtle and suggestive passage (246-249) an attempt is made to mediate between idealism and materialism. The result of the whole consummate being is exempt from change it cannot be devoid of life and motion. "Like children, Give us both," we say.

3. This leads up to the main question: (a) are different notions incompatible; or (b) is the idea of idealism independent and communicable, or (c) is there communication of some kinds and not of others? The last view alone tenable, and is confirmed by experience. And of the true combination and separation of kinds the philosopher is judge.

4. Then it is asked (in order to "bind the sophist") whether being is predicable of not-being.

Negation, falsity, contradiction, are three notions which Plato from his height of abstraction does not hold apart. His position is the converse of the Spinozistic saying, "Omnis determinatio est negatio." According to him, every negative implies an affirmative. And his main point is that true negation is correlative to true affirmation, much as he has said in the Phaedrus that the dialectician separates kinds according to the "lines and veins of nature." The Sophists is a standing protest against the error of marring the finely-graduated lineaments of truth, and so destroying the vitality of thought.

The Idealists whom the Eleatic stranger treats so gently have been identified with the Megarians. But may not Plato be reflecting on a Megarian influence operating within the Academy? Here, as partly already in the Parmenides and Theaetetus, the ideas assume the nature of categories, and being is the sum of positive attributes, while negation, as the shadow of affirmation, is likewise finally comprehended in the totality of being.

The remark made incidentally, but with intense emphasis, that the universe lives and moves "according to God," is an indication of the religious tone which reappears increasingly in the Politicus, Philebus, Timaeus and Laws. In passing on to consider the statesman, true and false, the Eleatic stranger does not forget the lesson which has just been learned. While continuing his method of dichotomies, he is careful to look on him with cold, and also with standing protest against the error of marring the finely-graduated lineaments of truth, and so destroying the vitality of thought. On the ethic-political side also a change has come over Plato. As he has stripped his ideas of transcendental imagery, so in reconsidering his philosopher-king he turns away from the smiling optimism of the Republic and looks for a scientific statesmanship that shall lay a strong grasp upon the actual world. He also feels more bitterly towards the demagogues and other rulers of Hellas. The author of the Politicus must have had some great quarrel with mankind. But so far as they will receive it he is still intent on doing them good.

1. The king is first defined as a herdsman of men, who as "slow bidets" are distinguished from the pig and the ape. But the king is not all in all to his charges, as the herdsman is. The above definition confuses human with animal, for whom the intermediate care of godly and happy, if they used their leisure in interrogating nature. But in this reign of Zeus it is far otherwise. Men have to order their own ways and try to imitate in some far-off manner all the but forms of divine rule

2. Therefore in our present definition the term "superintendent" must be substituted for "herdsman."

What special kind of superintendent is true statesmanship?

1. Soph. 265 D.
4. By way of an example, the art of weaving is defined. The example shows that kingscraft has first to be separated from other kinds of arts, both causal and conventional, and to adduce with it exhaustible social functions. Eight are eliminated, and the ninth, the class of ministers, remains. Of these (a) slaves, (b) hired men, (c) traders, (d) officials, (e) priests are again parted off, although the last are only barely distinguished from the king, when (f) a strange medley of monstrous creatures come into view. Some are fierce like lions, some crafty like the fox, and some have mixed natures like centaurs and satyrs. These are the actual rulers of mankind, and not discernible to the sophist himself. And they too must be separated from the true king.

5. The familiar tripartite distinction of monarchy, oligarchy, democracy, is doubled by introducing into each the distinction involved in the presence or absence of wealth, and in the observance or non-observance of law. But no one of the six carries in itself a scientific principle.

The true (a) government is the rule, not of many, but of one or of a few. "And they may govern, whether poor or rich, by free-will or compulsion, and either with or without law, so long as they govern scientifically."

6. The respondent, a youthful nameake of Socrates, is shocked at the remark that the true ruler may govern without law.

This leads to a discussion of the nature of law, which is compared to the prescription left by a physician. If present, he might dispense with his own art. So the presence of a competent ruler is better than the sovereignty of law, which makes no allowance for nature or circumstance, but tyrannically forces its own way. Imagine medicine, navigation, e.g., similarly conducted without penalties for innovation—what would become of civilization? Yet if law is disregarded by rulers who are unscientific and warped by self-interest, this leads to far worse evils. The presence of the observant character of law, therefore, is essential. Hence, in the continued absence of the true ruler, the best course, though only second best, is the strict observance of law. And he who so rules in humble imitation of the scientific governor may be truly called a king, although if the democratic lawyer were to appear his living would supersede the law.

7. As it is, though cities survive many evils, many more are shipwrecked because of the ignorance of those at the helm. The order of badness in the social state is:

- 1. Constitutional monarchy.
- 2. Constitutional oligarchy.
- 3. Law-abiding democracy.
- 4. Law-breaking democracy.
- 5. Tyranny.

8. It remains to separate from the true ruler those who co-operate with him as subordinates, the general, the judge, the orator. His own peculiar function is an art of weaving strength (the warp) with gentleness (the weft), when education has prepared them—and this (1) by administration, (2) by marriage.

The four preceding dialogues have shown (1) the gradual transformation of the Platonic ideas (while still objective) into forms of thought, (2) the tendency to group them into series of categories, (3) a corresponding advance in psychological classification, (4) an increasing importance given to method, (5) the inclination to inquire into processes (ψεῦδος) as well as into the nature of being.

Meanwhile Plato’s approach to the Eleatics, though in the way of criticism, has brought into prominence the notions of science, naturalism, being, sameness, difference, and has left somewhat in abeyance the idea of good. To this “highest of all studies” Plato now returns, equipped with his improved instruments, and ready to forge new ones in the same laboratory, or in some other, should occasion arise. His converse with Parmenides has added to his armoury an element of difference pervading all things, in other words, of an indeterminate element underlying all determinations. This brings him again into relation with the Pythagoreans, who had similarly asserted the combination of finite and infinite in the universe. Taking advantage of their help, he gains a more advanced (but still ideal) conception of the concrete harmony of things, and approaches the definition of that which in the Republic he but shadowed forth. With this most serious inquiry there is combined (as in the Sophist and Politic) an ironical and controversial use of dialectic, by which the juggler and false pretender (who is in this case the godless of pleasure), after claiming the highest place, is thrust down to the lowest.

It must be admitted that the style of the Philebus is far from brilliant, or even clear. In the effort of connecting abstractions Plato’s movement is more laboured than in his first glad realization of them.

Instead of attempting here to follow the windings of the dialogue, it must suffice to state the main result. Neither pleasure nor knowledge is the highest good, and the good eludes definition; but the shine, or habitation, of the good is a complex life of which the elements are, in order of merit: (1) measure, the cause of all right measure; (2) beauty, the effect, and (3) reality, the indispensable condition; (3) intellect; (4) science, art and right opinion; (5) pure pleasure unaccompanied with pain.

"Not all the animal kingdom shall induce us to put pleasure first."

The Philebus introduces us to the interior of the Academy in the lifetime of the master. More than any other of the dialogues it recalls Aristotle’s description of Plato’s teaching. But, while his followers seem early to have fallen under the dominance of the latter phase of his doctrine, Plato himself, even in the Philebus, is still detached from any servitude to the creations of his own mind. He manipulates them as the medium for expressing his fresh thoughts, but they are not yet crystallized into a group of certain sciences. As Renan says, "the most fatal error is to believe that one serves one’s country by calumniating those who founded it," neither is it for the interest of science to ignore these imperfect anticipations. By methods elaborated in the course of centuries, and far more sure than any which Plato had at his command, mankind have gained an extent of knowledge which he dreamt not of.1 But the Greek metaphysician is none the less a pioneer of knowledge,2 while the aporetic sciences of ethics and psychology had been carried from infancy to adolescence in a single lifetime.

VII. Timaeus, Critias [Hermocrates].—As the Sophists and Politic were written in continuation of the Theaetetus, so, at some uncertain point, Plato conceived the design of writing a great trilogy, for which the ideal state depicted in the Republic should be the point of departure. The grand outline there sketched by Socrates was now to be filled up by Critias and Hermocrates. The form set up by reasoning should be made alive, the "airy burghers" should be seen "making history." As a prelude to this magnificent celebration, Timaeus, the Pythagorean philosopher, who is present at the Panathenaea, is invited to discourse of the origin of all things, and to bring the glorious theme to the creation of man. What should have followed this, but is only commenced in the fragment of the Critias, would have been the story, not of a fall, but of the triumph of reason in humanity.

In the Philebus (50 A, cf. 62 D) Plato speaks with a touch of contempt of the life-long investigation of nature, as being concerned only with this visible universe, and immersed in the study of phenomena, whether past, present or to come, which admit of no stability and therefore of no certainty. “These things have no absolute first principle, and can never be the objects of reason and true science.”

Yet even this lower knowledge there is admitted as an element of that life which leads to an anticipation of the good. And there are not wanting signs in his later dialogues that Plato’s imagination had again been strongly drawn towards those physical studies which, as the Phaedo shows, had fascinated him in youth. That nature and the world proceed “according to God and not according to chance” is the belief of the Eleatic stranger, to whom he perceives that Theaetetus will be irresistibly drawn as he grows older (Soph. 265 D). In the midst of dialectical abstractions, the processes of actual production (ψεῦδος) have been increasingly borne in mind. And the myth in the Politicus turns on cosmological conceptions which, although differing from those in the Timaeus, and more accordant with Plato’s bitterest mood, yet throw a new light on the deeper current of

1 See however, Polit. 272 C, D.
2 See Jouett, Introd. to the Timaeus.
his thoughts. In the same passage (272 C) there occurs the first clear anticipation of an interroga­tion naturae.

The impulse in his new direction, if not originated, was manifestly reinforced, through closer intercourse with the Pythagorean school. And the choice of Timaeus the Pythagorean as chief speaker is an acknowledgment of this obvious truth. To Timaeus, of all the thinkers of the dialogue, there occur ideas apparently borrowed from the Pythagoreans, whom Plato per­ently ignored, this fact ought probably to be referred to some early reaction of Atomic on Pythagorean doctrine. It is important to observe, however, that not only the Timaeus, but the unfinished whole of which it forms the introduction, is pro­fessedly an imaginative creation. For the legend of prehistoric Athens and of Atlantis, whereof Critias was to relate what belonged to internal policy and Hermocrates the conduct of the war, would have been no other than a prose motion, a "mytho­logical lie," conceived in the spirit of the Republic, and in the form of a fictitious narrative. And, therefore, when time, Plato professes to give only a probable account of shadowy truths, he must be taken at his word, and not criticized in too exacting a spirit. His descriptions have much the same relation to the natural philosophy of Plato's time that Milton's cosmology has to the serious investigations of Galileo and Copernicus—except that all physical speculation hitherto partook in some measure of this half-mythological character, and that Plato's mind, although working in an unfamiliar region, is still that of a speculative philosopher.

As Parmenides, after demonstrating the nonentity of growth and decay, was yet impelled to give some account of this non-existent and unintelligible phenomenal world, so all the forms of the human mind are, in Plato's way, an attempt to give a probable and comprehensive description of the visible universe and its creation. In doing so he acknowledges an imperfect truth in theories which his dialectic had previously set aside. In examining the earlier philosophers he has already transgressed the limits prescribed by Socrates, and the effort to connect ideas has made him more and more conscious of the gap between the ideal and the actual. He cannot rest until he has done his utmost to fill up the chasm—calling in the help of imagination where reason fails him. His dominant thought is still that of a deduction from the "reason of the best," as in the Phaedo, or the "idea of good," as in the Republic. We find him and his absolute optimism were by this time considerably modified, and, although not confounding "causes with conditions," as he once accused Anaxagoras of doing, he yet assigns more scope to "second causes" than he would then have been willing to attribute to them. This partly comes of ripening experience and a deepening sense of the persistance of evil, and partly from the feeling—which seems to have grown upon him in later life—of the distance between God and man.

Timaeus. Plato, although warned off by Socrates, must needs attempt to give a probable and comprehensive description of the universe and its creation. In doing so he acknowledges an imperfect truth in theories which his dialectic had previously set aside. In examining the earlier philosophers he has already transgressed the limits prescribed by Socrates, and the effort to connect ideas has made him more and more conscious of the gap between the ideal and the actual. He cannot rest until he has done his utmost to fill up the chasm—calling in the help of imagination where reason fails him. His dominant thought is still that of a deduction from the "reason of the best," as in the Phaedo, or the "idea of good," as in the Republic. We find him and his absolute optimism were by this time considerably modified, and, although not confounding "causes with conditions," as he once accused Anaxagoras of doing, he yet assigns more scope to "second causes" than he would then have been willing to attribute to them. This partly comes of ripening experience and a deepening sense of the persistance of evil, and partly from the feeling—which seems to have grown upon him in later life—of the distance between God and man.

Timaeus begins by assuming (1) that the universe being corporeal is caused and had a beginning, and (2) that its mysterious author made it after an everlasting pattern. Yet, being truly visible, it can only be made the subject, humanly speaking, of probable discourse. Thus much being premised, he proceeds to unfold—(a) the work of mind in creation, (b) the effects of necessity, including their relation to the world of chaos, and (c) the points of departure of Platonism. A very few scattered observations are all that there is space for here.

1. In the mythology of the Timaeus some of the conceptions with which the Pythagorean clarity in the Sophist and Philebus resumé an ontological form. Thus, in compounding the soul-stuff of the universe, the father of all takes of the continuous and discrete and fuses them into an essence—the compound generative of all existing. Again he takes what identity as himself, and in the case of the other (cf. the Sophist), over­coming their inherent repugnance by his sovereign act.

2. The notion of an economy or of provision in Plato has been often exaggerated and misinterpreted. It is difficult for him of intentional obscurity in speaking of the creation of the Earth. It is clear, though Plato does not say so, that she is meant to have been created together with the Heaven and together with Time, and so before the other " gods within the heaven," i.e. the sun and moon and five planets, and it is a plausible supposition that she is the "artificer of day and night," by incising her bulk to the world. If the heavenly bodies are not the world-atoms (as Aristotle thought), it cannot be, as Grote supposed, a motion con­sentaneous with that of the outer sphere, but either some far slower motion, perhaps assumed in order to account for the shifting of the heavens, or a neutral motion, or the proper motion of the fixed stars, or one which is supposed to arise from the motion of the moon extending from the earth, the planets, and comprehending all.

3. Immortality is in the Timaeus dependent on the will of the Eternal. And the sublime idea of eternity is here first formulated. The immortality of the soul, however, is excluded among the works of reason, because the final cause of these higher senses is to give men perception of number, through contemplation of the measures of time.

4. It has been commonly said that the four elements of the Timaeus are geometrical figures, without content. This is not true. For what purpose does Plato introduce, "besides the archetype and the created form, a third kind, dim and hard to conceive, a sort of limbic or matrix of creation," if not to fill up the tringles which are elements of elements, and to be the vehicle of the forms compounded of them? It has been supposed that this "nurse of generation" is identical with "space," and it cannot be said that they are clearly kept apart by Plato. But he had a distinct nomenclature for either, and, although gravity is explained away (so that his molecules, unlike Clerk Maxwell's, may be called imponderable), yet by the time of filing particulars, the difference of his tables to the changing nature of the inferior gods, but they also create the lower and mortal parts of the human soul: the principle of anger which is planted in the breast, within hearing of reason, and that of appetite which is lodged below the diaphragm, acting like an anxiety to the stomach and giving a hankering after a crumb of bread, and the liver for a "soothing" glass-looking to soothe or terrify it when tempted to break loose.

5. The brain-pam was left bare of protecting flesh "because the soul is colored who forms a sort of armor for us a precious life with capability of reason, in preference to a long secure existence with obstruction of thought."

6. The nails are a rudimentary provision for the lower animals, into which the degeneration there afterwards to be transformed.

7. Vegetables have sensation but no motion.

8. By way of illustrating the very curious account here given of respiration, it is suggested that the supposed difference between the attraction of the magnet is really due to rotatory motion and displacement; a remarkable anticipation (Tim. 80c).

9. When the original particles wear out, and the bonds of soul and body in the marrow give way, the sick observation flies away. This is the painless death of natural decay.

a. 1. The dependence of mental disease on bodily conditions is more fully recognized in the Timaeus than elsewhere in Plato (contrast the Charides, for instance).

b. He has also changed his mind about the treatment of disease, and shows more respect for regimen and diet than in the Republic. Diseases are a kind of second nature, and should be treated accordingly.

c. It is also a remark in contrast with the Republic, that over­study leads to head complications, which physicians ascribe to chill and find intractable. Lastly, it is one of the strange irregularities in the composition of the Timaeus the creation of the woman and the relation of the sexes to each other are subjects reserved to the end, because this is the place given of the fable that is unusual for the woman: it is the first transmigration from the form of man. This order is probably not to be attributed to Plato's own thought, but to some peculiarity of Pythagorean or Orphic tradition.

VIII. The Laws.—The two series of dialogues, the dialectical and the imaginative—Sophists, Politicians, Philosophos—Timaeus, Critias, Hermocrates—were left incomplete. For Plato had concentrated his declining powers, in the evening of his life, in a grand and vast attempt to frame a full account of society which was to be common to all the nations of the world. The Laws is a complete system of laws and customs which Plato would have imposed upon the world. It is like the The Republic, a supplement to his lost drama, but the dramatic element has been entirely left out. And, as in the Republic, the hero makes his appearance only towards the close of the work. And it is a strange and singular fact that of the last six books of the Law, the first three are almost a facsimile of the Philebus, and the last three a facsimile of the Sophist. It is, in fact, a sort of appendix to the Republic, which is of course a part of the Laws, and the whole body of dialogues is a mere attempt to decide on the best form of government and the best society, as well as to propose a system of law and morals for the individual.
his life, 1 upon a different task. He was resolved to leave behind him, if he could so far overcome the infirmities of age; 2 a code of laws, conceived in a spirit of concession, and such as he still hoped that some Hellenic state might sanction. The motive for this great work may be gathered from the Politicus. The physician in departing is to give a written prescription, adapted as far as possible to the condition of those from whom he goes away. This is the second-best course, in the absence of the philosopher-king. And, as the Hellenic world will not listen to Plato's heroic remedy, he accommodates his counsel to their preconceptions. He returns once more from abstract discussions to study the application of ideas to life, and though, by the conditions of the problem, his course is "nearer earth and less in light," this long writing, which is said to have been posthumous, 3 has a peculiar interest. The ripeness of accumulated experience and the mellowness of wise contemplation make up for the loss of prophetic insight and poetical charm.

The form of dialogue is still retained, and an aged Athenian is imagined as discouraging legislation with the Lacedaemonian Megillus and the Cretan Clytias, who has in view the foundation of a new colony, and is on his way with his two companions from Cnosus to the temple and oracle of Zeus.

Plato now aims at moderating between Dorian and Ionian law, freely criticizing both, and ranging on them from a higher point of view. "The praise of obedience, the authority assigned to elders, the prohibition of divorces, the enforcement of marriage, the common meals, the distribution and inalienability of land, the institution of the Cryptea, the freedom of bequest to a favourite son, the dislike of city walls—all reflect the custom of Sparta." 4 . . . . . The "use of the lot, the scrutiny of magistrates, the monthly courses of the council, the pardon of the forgiven homicide, most of the regulations about testaments and the guardianship of orphans, the degrees of consanguinity recognized by law, correspond to Athenian laws and customs" (Jowett).

The philosopher's own thoughts come out most strongly in the "prules" to the laws, 5 and in the regulations concerning education, marriage and the punishment of impiety (i.e. 1st, atheism; 2nd, denial of providence; 3rd and worst, immoral superstition). The difficulty which is met in the Politicus by the abandonment of the world for a time, and in the Timaeus by the lieutenantcy of lower gods, here leads to the hypothesis of an evil soul. The priority of mind (often before asserted) and the increasing importation attached to numbers are the chief indications of Plato's latest thoughts about the intelligently created world. But it must be remembered that the higher education (answering to Rep. vi., viii.) is expressly reserved. 6 Had Plato written his own Epinomis, the proportions of the whole work (not then "achecal"s) might have been vastly changed.

The severity of the penalties attached to the three forms of heresy, especially to the third and worst of them, has led to the remark that Plato, after asserting "liberty of prophecying," had become intolerant and bigoted in his old age (Grote). But the idea of toleration in the modern sense was never distinctly present to the mind of any ancient philosopher. And, if in the Laws the lines of thought have in one way hardened, there are other lines in which both the author and the reader have seen the "second-best" constitution contains a provision, which was not admissible in the "perfect state," for possible changes and readaptations in the future. The power of self-reformation is hedged round indeed with extreme precautions; and no young or middle-aged citizen is ever to hear a word said in depreciation of any jot or tittle of the existing law. But that it should be provided, however guardedly, that select commissioners, after travelling far and wide, should bring back of the fruit of their observations for the consideration of the nocturnal council, and that a power of constitutionally amending the laws should be admitted into the state, is sufficiently remarkable, when the would-be finity of ancient legislation is considered. Plato even comes near to the reflection that "constitutions are not made, but grow" (iv. 700 A).

Plato in the Laws desists finally from impersonating Socrates. But he has had some master in spirit than whom he composed the Praedaeus. The sympathy with common laws, the acceptance of Greek religion, the deepening humanity, are no less essentially Socratic than the love of truth which breathes in every page. And some particular aspects of Socratism reappear, such as the question about courage 7 and that concerning the unity of virtue.

Doubtful and Spurious Works.—Of the dialogues forming part of the "Platonic canon," and not included in the preceding survey, the Lesser Hippias, First Alcibiades and Menexenus are the most Platonic, though probably not Plato's. The Greater Hippias and the Chiliaon are also admitted to have some plausibility. The Second Alcibiades (on Prayer), the Hipparchus (touching on Peisistratus and the Homogeneity of the Gods), Epinomis, Epistae, Theages, are generally condemned, though most of them are very early forgeries or academic exercises. And the Aixioteus (though sometimes prized for its subject, "the contempt of death"), the De justo, De virtute, Demodocus, Sisyphus, Eryxias (a not-uninteresting treatise on the use of money), together with the so-called Definitions, were rejected in ancient times, and are marked as spurious in the M.S.

Editions.—(1) Complete: Aldine, Ven., 1513: H. Stephonus, Vols. (1579), with Latin version by Serranus (cf. Le Serre, the real editor). The paging of this edition is preserved as reference on the margins of most subsequent editions); G. Stallbaum, 12 vols., 1821-1825; G. Stallbaum, the text in 1 vol. (1905); C. F. Hermann; 8 vols., 1898-1903; C. E. Schurzer; 15 vols., 1876-1882; G. H. A. Hermann, 1930; G. Gomperz, 1931. The edition of the 19th century by Baltier, Orelli and Winkelmann (1839-1842); Hirschig and Schneider, in Didot's series (1850-1875); M. von Schanz, with critical notes (1875-1887); J. Burnet (Oxford, 1902). (2) Partial: L. E. Heindorf, Lysis, Charmides, Hippias Maior, Phaedrus, Gorgias, Theaetetus, Cratylus, Parmenides, Euthydemus, Phaedo, Sophists, Protagoras; Philebus, C. Badham, E. Poste (1861), R. G. Bury; Apologia, J. Riddell (with Digest of Platonic Idioms) (1861); Protagoras, Wayte (1854); Theaetetus, L. Campbell (1861) 8; B. Kennedy; Sophists and Politicus, L. Campbell (1867); Phaedo, W. Geddes, Archer Hind; Timaeus, Archer Hind (1888); Parmenides, Waddell (1894); Mem. J. Adam, Seymour Thompson; Apologia, Crito, Euthyphro, E. Poste; Stoek: Phileb; D. Kennedy; Epicurus; Symposium, Euthydemus, Laches, C. Badham; Parmenides, Stallbaum, Maguire, Waddell, Leges, F. Ast (1894); C. Leonard's Edition (1896); Republic, Jowett and Campbell (1894). J. Adam (1902).

Translations.—Latin: A Latin version of the Timaeus by Chalcidius existed in the middle ages and was known to Dante. It was printed at Paris in 1520 (Teubner, 1876). The complete rendering by Marangolo Picino (1496) formed the basis of other Latin translations, such as that of Serranus (stipu), which accompanied the edition of Stephanus. It was printed in the Basel edition of 1553. English: (1) Complete: Sydenham and Taylor (1804); Jowett (1871-1892). (2) Partial: Republic, D. Vaughan and Jowett (in a separate volume; 3rd ed., 2 vols., 1908); Philebus, E. Poste; Georgias, Copo; Timaeus, Archer Hind (in his edition); Protagoras, C. E. Schurzer; Philebus; Conybeare; Gorgias; Plato's Three last Dialogues, 1876. Thompson; Symposium, Euthydemus, Laches, C. Badham; Parmenides, Stallbaum, Maguire, Waddell, Leges, F. Ast (1894); C. Leonard's Edition (1896); Republic, Jowett and Campbell (1894). J. Adam (1902).

tiones Platonicae (1820); M. Schanz's edition with critical notes;
edition. The important Codex Clarkianus in the Bodleian library
has been reproduced in facsimile, with a preface by T. W. Allen
(1898-1899).

PLATO, Athenian comic poet of the Old Comedy, flourished
between 425-380 B.C. According to Suidas, he was the author of
ten comedies. Some of these deal with political matters. Such
were the Cleophon and Hyperbolus, directed against the
well-known demagogues, and the Symmachia, referring to a
coalition formed by Nicias, Alcibiades and Phaex to get rid
of Hyperbolus by ostracism. His later plays treat the vices
and failings of mankind in the spirit of burlesque and parody.
Such were the Sophistes, akin to the Clouds of Aristophanes;
the Cinesias, an attack on a contemporary poet; the Festivals,
satirizing the useless expenditure and extravagance common on
such occasions; mythological subjects—Adonis, Europe, Io,
the Auts (on the Aeginetan legend of the change of ants into
men); Phaon, the story of the Lesbian ferryman, who was
presented by Aphrodite with a marvellous ointment, the use of
which made women madly in love with him.

See T. Kock, Comicon criticismorum fragmenta, i. (1880); A.
Meineke, Poetorum comicorum graecorum fragmenta (1893).

PLATON, LEVSHIN (1733-1812), Russian divine, was born at
Chaskhinkovo near Moscow, and educated in the academy of
that city. In 1763 the empress Catherine II. invited him to
instruct her son Paul in theology, and he became one of the
court chaplains. Three years afterwards Platon was appointed
archimandrite of the monastery of Grumman, and in 1786
bishop of Labrador. In 1778 he was consecrated archbishop of
Tver, and in 1787 archbishop of Moscow and metropolitan.
He died in 1812, one of his last acts having been to write an encouraging letter
to the emperor Alexander I. in view of the French invasion.
Platon was a brilliant and learned man, and the author of several
works which enjoyed a high reputation in their time, including
A Short History of the Russian Church, which has been translated
into English.

PLATONIC LOVES, a term commonly applied to an affectation
relation between a man and a woman into which the sexual
element does not enter. The term in English goes back as far
as Sir William Davenant's Platon's lovers (1662-1668); E. Albert,
from a passage in Plato's Symposium, of the love of the
idea of good which lies at the root of all virtue and truth.
Amor platonicus was used, e.g. by Marzillo Ficino (15th century),
as a synonym for amor socraticus, referring to the affection
which subsisted between Socrates and his pupils.

PLA ToOn (Fr. peloton, from Fr. pelele, a ball or pellet; cf.
Ger. Haufe, heap), a small group of soldiers. In the early
17th century it was a definite tactical unit of infantry, corre-
ponding to the modern section or half company. In the 18th
century the battalion, irrespective of its organization into
companies, was told off on parade into six, eight or ten platoons
of equal strength. "Platoon fire" was the systematic and
regulated fire of platoon volleys, the platoons firing one after
the other. Hence a "platoon" sometimes means a volley.

The fire of a long line of infantry was as a rule conducted on
the same principles, each battalion of the front line employing
platoon fire, which is often picturesque described as a "rolling
platoon fire," or "rolling volleys." The word is obsolete in
the British army, but is used in the United States, and, in various
forms, in the armies of France and other Latin nations.

PLATT, THOMAS COLLIER (1833-1910), American politician,
was born in Owęgo, Tioga county, New York, on the 15th of July
1833. He studied in 1849-1852 at Yale, from which he received
the honorary degree of A.M. in 1876. He made money in lumbering
out West, and returning to Owęgo became a banker and
railway director. He helped to organize its Republican party in
Tioga county, and in 1872-1877 was a representative in Congress.
In 1877 he was chairman of the state Republican Convention at
Rochester. On the 18th of January 1881 he was elected United
States senator, but resigned, with his colleague, Roscoe Conkling,
the 16th of May following, chiefly because President Garfield,
in spite of their protest, had appointed as collector of the port
of New York, Judge William H. Robertson, a political opponent.
Within ten years he became the acknowledged Republican
boss of the state, and he again served in the United States Senate
from 1897 to 1906. But his power waned steadily after
about 1905. He died in New York City in the 6th of March
1910.

PLATTE (so named, from the French, because of its shallowness),
or NEBRASKA, a river system of Colorado, Wyoming and
Nebraska, tributary to the Missouri river, which it enters
immediately north of Plattsburgh, Nebraska, 18 m. below
Omaha, in about 41° 3' N. lat. Including the North Platte it
is about 900 m. long from its headwaters, with a drainage
basin for the entire system of 90,000 sq. m. The Platte proper
is formed by the junction of the North Platte and the South
Platte, sometimes called the North and South Forks of the
Platte, immediately below the city of North Platte in Lincoln
county, Nebraska. The North Platte and South Platte rise
respectively in North Park and South Park in Colorado. The
tributaries of the main stream all flow in from the north; the
most important being the Loup, which empties immediately
east of Columbus in Platte county, and the Elkhorn, which
joins the Platte in Douglas county, due west of Omaha.

See J. C. Stevens, Surface Water Supply of Nebraska (Washington,
1899).

PLATTSBURG, New York, a city, of entry and the county-seat of
Clinton county, New York, U.S.A., situated on the west shore
of Lake Champlain, at the mouth of the Saranac river, 168 m.

PLATTEN, KARL FRIEDRICH (1800-1858), German
metallurgical chemist, was born at Kleinwaltheroth, near
Freiberg in Saxony, son of Joh. C. Plattner, an iron and
coal working miner, found the means to have him educated first at the Bergschule and then at the Berg-
Akademie of Freiberg, and after he had completed his courses there in 1820 he obtained employment, chiefly as assayer, in
connexion with the royal mines and metal works. Having taken
up the idea of quantitative mouth-blowpipe assaying, which was
then almost unknown—except that E. Harkort (1797-1835)
in 1827, while a student in Freiberg Academy, had worked out a
blowpipe assay for silver—he succeeded in devising trustworthy
methods for all the ordinary useful metals; in particular his
modes of assaying for nickel and cobalt quickly found favour with
metallurgists. He also devoted himself to the improvement
of quantitative blowpipe analysis, and summed up his experience
in a treatise Die Proberkunst mit dem Lüthrohr (1835),
which became a standard authority. In 1840 he was made chief
of the royal department of assaying. Two years later he
was deputed to complete a course of lectures on metallurgy at
the Bergakademie in place of W. A. Lampadius (1772-1842), whom
he subsequently succeeded as professor. He died at Freiberg
on the 22nd of January 1858.

In addition to many memoirs on metallurgical subjects he also
published Die metallurgischen Rostprozesse theorisch betrachtet
(1824), and posthumously Vorlesungen über allgemeine Röntgenkunde
(1860).
PLATTSMOUTH—PLATYELMIA

(by rail) N.N.E. of Albany. Pop. (1890), 7026; (1900), 8434, of whom 1953 were foreign-born; (1910), census, 11,138. It is served by the Delaware & Hudson railway, and has steam connectors with lake ports. Its situation in the region of lakes and mountains and its delightful climate have made it a summer resort. Among its institutions are the Samuel F. Vilas Home (for aged and infirm women); the Home for the Friendless of Northern New York (1874), for the care of homeless children; the Plattsburg State Normal and Training School, the D'Youville Academy for girls (founded in 1860, chartered in 1871), under the direction of the Grey Nuns; the College St Pierre (Roman Catholic, 1905), and the Champlain Valley Hospital. The barracks, about a mile away, is an important military post. Champlain, one of the oldest boroughs in the Roman Catholic, 1905, is the site of the Catholic summer school. Plattsburg has a fine harbour and is the port of entry of the Champlain customs district; in 1906 its exports were valued at $15,169,502 and its imports at $8,167,527. Among the city's manufactories are lumber, wood pulp, paper, shirts, sewing-machines and automobiles. The total value of the factory products in 1905 was $1,936,702.

Plattsburg was incorporated as a village in 1705, and derived its name from Zephaniah Platt (1740-1807), who had led a colony of settlers to this place from Long Island; it became a city in 1902. About Valcour Island (5 m. south-east of Plattsburg) on the 11th of October 1776, a British fleet under Captain Thomas Pringle and an American flotilla under Benedict Arnold engaged in the first conflict between American and British fleets, the British being victorious. On the outbreak of the War of 1812 the village became the headquarters of the American army on the northern frontier. On the 11th of September 1814, in Plattsburg (or Cumberland) Bay, Captain George Downie, commanding a British flotilla, was defeated by an American flotilla commanded by Commodore Thomas Macdonough, losing his life in the engagement (see Champlain, Lake).

PLATTSMOUTH, a city and the county-seat of Cass county, Nebraska, U.S.A., situated in the valley and on the bluffs of the Missouri river near the mouth of the Platte. Pop. (1900), 4064, of whom 979 were foreign-born. It is served by the Chicago, Burlington & Quincy, and the Missouri Pacific railway systems. There are railway car-shops, and a considerable trade is done in grain and cattle. A trading-post licensed by the United States government was opened here in 1833, and a town platted in 1834. Plattsburg was first incorporated as a city in 1835, being one of the oldest settlements and cities of the state.

PLATYELMIA, a phylum of the animal kingdom which comprises three classes, the Planarians, Trematodes (q.v.) and Cestodes. It is the group of animals in which the act of creeping has first become habitual. In association with this movement in a definite direction the body has become veriform and bilaterally symmetrical. One end of the body, through contact, during locomotion, with fresh tracts of medium and other forms of stimuli, has become more specialized than the rest, and here the nervous system and sense-organs are more densely aggregated than elsewhere, forming a means of controlling locomotion and of correlating the activities of the inner organs with the varying stimuli that impinge upon the body. The form and habits of the group vary widely. The Planarians are free-living animals, the Trematodes are parasitic upon and within animals, and the Cestodes are wholly endoparasitic.

Structure.—The chief features which Platyelmina possess in common are the following. The body is not metamERICALLY segmented and is composed of a muscular tunic covered externally by a more or less modified cellular layer. Within this muscular layer lies a parenchymatous tissue which may be uniform (Cestodes) or differentiated into a central or digestive, and a peripheral portion (some Turbellaria), or finally the central portion becomes tubular and forms the digestive sac (Trematodes), while the peripheral portion is separated from it by a space lined in some forms by a flattened epithelium (most Planarians). It is characteristic of the group that the mouth should be the only means of ingress to and egress from the digestive sac and that no true perivisceral space or coelom exists in the sense in which these terms are used in higher Invertebrates. The peripheral parenchyin give rise to protonphidia, that is to coiled tubes commencing in periviscer cells containing a flame-like bundle of cilia and provided by branched outgrowths and communicating with the exterior by long constricted canals which open at the surface of the body. These protonphidia are the excretory organs. The nervous system, though centralised at one end of the body, contains diffused nerve-cells in the course of its tracts, which are disposed in two or more longitudinal bands interconnected by transverse bands. The Platyelmina are hermaphrodite and the reproductive organs are complex. The male organs consist of paired testes communicating by delicate canals with a protrusible penis. This organ is generally single but sometimes paired and occasionally multiple. It is frequently armed with spines, hooks or stykelet, and is further complicated by the addition of a nutritive secretion (the prostate gland) which may open at its base or pass separately by a special duct to the exterior. There is some reason to believe that this complicated and variable apparatus is used for stabbing the body of another animal and that beginning as a weapon for catching prey it has become modified for hypodermic impregnation and only gradually adapted for insertion into the bursa copulatrix. The female organs are no less complex. They consist of solid or tubular ovaries which may be single, double or multiple. In the majority of Platyelmina the primitive ovary becomes divided into fertile and sterile portions, i.e. into distinct ovarian and vitellarian regions. The yolk prepared by the latter is conducted by one or more specialized ducts to the oviduct and the point of union is distinguished by the opening of a "shell-gland" which secretes a membrane around the conjointed mass of ovum and yolk. From this junction there proceeds an oviduct or "uterus" (paired or single) which before opening to the exterior expands to form a muscular protrusible pouch—the bursa copulatrix. Frequently also from this junction of the ovaries and the vitellaria a median tube is given off which either opens to the exterior or into the intestine, in the latter case it appears to serve as means of conveying superfluous yolk to the gut, where it may serve as food.

Inter-relations.—The inter-relations of the three members of the Platyelmina are of a more doubtful nature than is the unity of the phylum. The Turbellaria undoubtedly form the most primitive division as is shown by their free-living habits, ciliated sense-organs and sense-organs. The Trematodes are somewhat modified in accordance with their ecto- or endoparasitic life, but they exhibit such a close similarity of structure with the Turbellaria that their origin from Planarians can hardly be doubted, and indeed the Tennocephaloidea (see Planarians) form an almost ideal annelid group linking the ectoparasitic Trematodes and Rhabdocoepl Planarians. The Cestodes, however, are connected by no and intermediate forms with the other Platyelmina. Their adaptations to parasitic life in vertebrate animals appear to have involved such modifications of structure and development that their affinities are quite problematical. The entire absence of any trace of a distinct alimentary tract, the loss of true generative power, the peculiar gametic segmenta-

FIG. 1.—Free-swimming Larva (Müller's Larva) of a Polyclad Planarian to illustrate the trochosphere-hypothesis of the origin of the Platyelmina. The larva is seen in optical sections, and its distinguishing feature is the ciliated lobed band (el, sl, dl), which corresponds to the pre-oral ciliated band of a trochosphere-larva. It is here drawn out into eight processes, of which six are shown, their continuity being expressed by the dotted line.

(From Cambridge Natural History: "Worms, etc." by permission of Macmillan & Co., Ltd.)
one extremity, and the absence of any morphologically distinct anterior extremity, are adaptations to the wholly parasitic life of this class. Their structure is similar to that of Trematodes, from which in the opinion of most zoologists they have been derived.

Affiniates.—As the Turbellaria (Planarians) are the most primitive division of the Platyhelminthes, the problem of the affinities of this phylum resolves itself into that of the relationships of the Turbellaria. With regard to the origin of this class two divergent views are still held. On the one hand the Turbellaria are considered to be an offshoot of the early Coelomate stock, on the other they are held to be descendants of a simpler two-layered stock. The former hypothesis with its variants may be called the Trochosphere-hypothesis, the latter the Gastraea-hypothesis. The Trochosphere-hypothesis (2), (3) is based chiefly on the occurrence in certain Polyclad Turbellaria, of a larval form (Müller's larva) which is comparable to a certain stage (pro-trochula) in the development of the Trochosphere-larva. This Trochosphere is the characteristic larva of Mollusca, Annelida and some Gephyrae; and the Rotifera appear to remain throughout life as modified Trochospheres. It is a top-shaped, free-swimming organism provided with a proral band of cilia, an apical sense-organ, a simple gut, protonephridia and schizocoel. The importance of this resemblance between the Polyclad larva and the Trochosphere-larva of higher invertebrates is increased if the widely adapted view (held on other grounds) that the Polyclads are the most primitive of the Turbellaria, is soundly based. The grounds for this view are the radial symmetry of several Polyclads and the supposed origin of gonads and excretery flame-cells from the walls of gut, the occurrence of nematomes of the same radiate construction Polyclads, and lastly the presence of two peculiar animals Ctenophora and Coleochoanthes, which suggests a transition from Ctenophora to Polyclads. At the present time, however, none of these grounds is proved, but the last-named hypothesis is about ten years ago (4). The argument has come to rest on the agreement between the cell-lineage of Polyclads and that of certain Mollusca and Annelids. This resemblance is considered by Hubrecht (5) to be one of the ground-forms for concluding that the Polyclads are an offshoot, and possibly a degenerate offspring, from the early Coelomate stock.

The Gastraea-hypothesis is founded on quite other considerations. In effect (6) it traces the Turbellaria to small two-layered organisms consisting of a layer of epidermis and a central syncytial tissue. Such an organism is found in the peculiar Trichoplax, Lohmanniella, &c. The early stages of most animals pass through such a stage, which is known as a "pluteus." From such branching forms the evolution of the Turbellaria leads first through the Acoelous forms in which the central syncytium is partly differentiated into digestive, muscular and skeletal tissue, then to the more specialized Rhabdocoela, and so through the Allocoelous to the Tricladans and finally to the Polyclads. The careful study of the development of one Acoelous form and of certain Rhabdocoels has strengthened this hypothesis by showing that no definite enteron or gut was a part of that first laid down in the syncytium; that certain elongate forms in this tissue are transformed into digestive tracts, others excretery, others again muscular. The study of Rhabdocoels (7) has led to the important discovery that the rudiment of the gonads and that of the pharynx are the first cells to appear, and that the gonadal and pharyngeal indentations develop independently of them. This segregation of the germ cells and their independence of the intestinal sac is an indication that the origin of these organs is not connected with the digestive tract, and until we have more information as to the evolution of the complex genitalia of the higher Turbellaria we cannot hope to understand the presence of such highly modified structures in animals of an otherwise low grade or organization.

LITERATURE.—Recent discussions of the affinities of the Platyhelminthes will be found in (1) A. Sedgwick, Textbook of Zoology (1868), i. 212; (2) Hartsch, Lehrbuch der Zoologie (1891), pp. 319-320; (3) Trilobata, and (4) Trochosphere. In "Treatise on Zoology" (1900), p. ii. Introduction and ch. viii. pp. 15-19; (5) A. W. Hubrecht, Jenaische Zeitschrift für Naturwissenschaft (1905), pp. 151-156; (6) W. Graff, Adolf Graffs Handbuch der Systematischen Zoologie, ed. 6, p. 136; (7) Bengel, Das Entwickele des Rhabdocoelidæ sec (7) Brejazal, Zeitschrift für wissenschaftliche Zoologie (1904), vol. 76.

PLATYPUS. The duck-billed platypus (Platypus anatinus) was the name assigned to one of the most remarkable of known animals by George Shaw (1740-1832), who gives an account of it to the muscetect of the scientific world in the Naturalist's Miscellany (vol. x., 1799). In the following year it was independently described by Blumenbach (Vegeta Magazin, ii. 205) under the name of Ornithorhynchus paradoxus. Shaw's generic name, although having priority in that of Blumenbach, could not be retained, as it had been used at a still earlier time (1763) by Herbst for a genus of Coleoptera. Ornithorhynchus (Gr. ὄρνις, bird, and χυός, bill) is therefore now universally adopted as the scientific designation, although duck-billed platypus (Gr. ναζη, flat, and ρός, foot) may be conveniently retained as a vernacular appellation. The common name is called "water-mole," but its affinities with the true moles are of the slightest and most superficial description. The anatomical differences by which the platypus, and its only allies the echidnas, are separated from all other mammals, so as to form a distinct sub-class, are described in the article MONOTREMATA, where also will be found the main distinctive characters of the two existing representatives of the group. It is there stated that the early stages of the development of the young are not yet fully known. Sir R. Owen, and later E. B. Poulton, showed that the ovum of the platypus was large compared with that of other mammals, while another, also well shown that it was filled with yolk, and that it was surrounded by a shell that Platyphus as well as Echidna is oviparous. Two eggs are produced at a time, each measuring about three-fourths of an inch in its long and half an inch in its short axis, and enclosed in a strong, flexible, white shell.

The platypus is pretty generally distributed in situations suitable to its aquatic habits throughout the island of Tasmania and the southern and eastern portions of Australia.
The length of the animal when fully grown is from 18 to 20 in. from the extremity of the beak to the end of the tail, the male being slightly larger than the female. The fur is short, dense and rather soft to the touch, and composed of an extremely fine and close under-fur, and of longer hairs which project beyond this, each of which is very slender at the base, and expanded, flattened and glossy towards the free end. The general colour is deep brown, but paler on the under parts. The tail is short, broad and depressed, and covered with coarse hairs, which in old animals generally become worn off from the under surface. There are no true teeth in the adult, although the young possess a set which are shed after being worn down by friction with food and sand, their purposes being afterward served by horny prominences, two on each side of each jaw—those in the front narrow, longitudinal, sharp-edged ridges, and those behind broad, flattened and molariform. The upper surface of the lateral edges of the mandible has also a number of parallel fine transverse ridges, like those on the bill of a duck. In the cheeks are tolerably capacious pouches, which appear to be used as receptacles for food.

The limbs are strong and short, each with five well-developed toes provided with strong claws. In the fore feet the web not only fills the interspaces between the toes, but extends considerably beyond the ends of the long, broad and somewhat flattened nails, giving great expanse to the foot when used for swimming, though capable of being folded back on the palm when the animal is burrowing or walking on the land. On the hind foot the nails are long, curved and pointed, and the web extends only to their base. On the heel of the male is a strong, curved sharply pointed, movable horny spur, directed upwards and backwards, attached by its expanded base to the accessory bone of the tarsus. This spur, which attains the length of nearly an inch, is traversed by a minute canal, terminating in a fine longitudinal slit near the point, and connected at its base with the duct of a large gland situated at the back part of the thigh. The whole apparatus is so exactly analogous in structure to the poison-gland and tooth of a venomous snake as to suggest a similar function, and there is now evidence that it employs this organ as an offensive weapon.

The platypus is aquatic in its habits, passing most of its time in the water or close to the margin of lakes and streams, swimming and diving with the greatest ease, and forming for the purpose of sleeping and breeding deep burrows in the banks, which generally have two orifices, one just above the water level, concealed among long grass and leaves, and the other below the surface. The passage at first runs obliquely upwards in the bank, sometimes to a distance of as much as 50 ft., and expands at its termination into a cavity, the floor of which is lined with dried grass and leaves, and in which, it is said, the eggs are laid and the young brought up. Their food consists of aquatic insects, small crustaceans and worms, which are caught under water, the sand and small stones at the bottom being turned over with their bills to find them. They appear at first to deposit what they have thus collected in their cheek pouches, and when these are filled they rise to the surface and quietly triturate their meal with the horny teeth before swallowing it. Swimming is effected chiefly by the action of the broad forepaws, the hind feet and tail taking a little share in locomotion in the water. When asleep they roll themselves into a ball, as shown in the figure. In their native haunts they are extremely timid and wary, and very difficult to approach, being rarely seen out of their burrows in the daytime. Mr A. B. Crowther, who supplemented the often quoted observations of Dr George Bennett upon the habits of these animals in confinement, states: "They soon become very tame in captivity; in a few days the young ones appeared to recognize a call, swimming rapidly to the hand paddling the water; and it is curious to see their attempts to procure a worm enclosed in the hand, which they greedily take when offered to them. I have noticed that they appear to be able to smell whether or not a worm is contained in the closed hand to which they swim, for they desist from their efforts if an empty fist was offered." (W. H. F.; H. Sc.)

PLAEN, a town of Germany, in the kingdom of Saxony, on the Weisse Elster, 60 m. south of Leipzig, on the railway to Hof and Munich and at the junction of lines to Eger and Gera. Pop. (1890), 47,097; (1900), 73,801; (1901), 105,732. It was formerly the capital of Vogtland, or Voigtlând, a territory governed by the imperial voig, or bailiff, and this name still clings in popular speech to the hilly district in which the town lies. Of its three Evangelical churches the most prominent is the fine Gothic church of St John, with twin spires, which was restored in 1856. Other buildings of note are the town hall, dating from about 1550; and the old castle of Hradisch, now used as a law court. Plauen is now the chief place in Germany for the manufacture of embroidered white goods of all kinds, for the finishing of woven cotton fabrics, known as Plauen goods, and for the making of lace. Plauen was probably founded by the Slaves. It was first mentioned in 1132, it passed under the authority of Bohemia in 1377, and came to Saxony in 1466, remaining permanently united with the electorate since 1560. The manufacture of white goods was introduced by Swabian, or Swiss, immigrants about 1570. The advance in its material prosperity has been especially rapid since the incorporation of Saxony in the German Zollverein.

See Fiedler, Die Stadt Plauen im Vogtland (Plauen, 1874); and Beiträge zur Geschichte der Stadt Plauen (Plauen, 1876); Metzner, Führer durch Plauen (1903); and the publications of the Allgemeine Volksverein in Plauen.

PLAUTUS, TITUS MACCIUS (originally perhaps Macceus; cf. Asin. Proli. 11), the great comic dramatist of ancient Rome, was born at Saris in Umbria according to the testimony of Festus, who calls him Umber Sarasinus, and Jerome. The date of his birth depends upon an inference based on the statement of Cicer (De senectute, xiv. 50) that he was an old man when he wrote his Truculentus and Pseudolus. The latter play was

Some doubt has been expressed as to whether the eggs are extruded or hatched within the body. At a scientific meeting of the Zoological Society of London, on the 17th of December 1901, Mr Oldfield Thomas read a letter from Mr G. Metcalfe, who had lived many years in a region inhabited by these animals. He had made special inquiries of the authorities of the Sydney, Melbourne, Brisbane and Hobart museums, and published questions in the new evidence has reached him that both the Ommatophorus and Ornithorhyncus have ever been obtained except by the dissection of the mother. Mr Thomas laid stress on what had been advanced on the other side (Philosophical Transactions, clxxxviii. 463). Professor Spencer (Nature, xxx. 152) and Mr J. Douglas Ogilby (Catalogue of Australian Mammals, p. 1, Sydney, 1902), but expressed the hope that further inquiries might be made by naturalists in Australia as to the actual finding of such eggs in the burrows, so that this most interesting point might be finally settled.
But as a translator Plautus is nothing less than masterly. His command of the art is such that his plays read like original works, and it may be at least said that some of his characters and plots are so vividly from his canvas that they have ever since served as representatives of certain types of humanity, e.g. Euculio in the Aulularia, the model of Molère's miser. Alliteration, association, plays upon words and happy coinages of new terms, give his plays a charm of their own. "To read Plautus is to be once for all disabused of the impression that Latin is a dry and uninteresting language" (Skutsch, in Die Cultur der Gegenwart; 1905). It is a mistake to regard the Latin of Plautus as "vulgar" Latin. It is essentially a literary idiom, based in the main upon the language of intercourse of the cultivated Roman society of the day (cf. Cic. De oratore, iii. 45; 60, etc.). In the passage of the Bacchides, though the characters in this pistrinum he wrote three of his plays (the Saturio, the Addictus and another). The main body of his works belongs, so far as can be ascertained from the scanty evidence which we have, to the latter half of his life; 206 B.C. is the approximate date of the Miles gloriosus; cf. line 211 seq., qui bini extodes . . . occubant (present tense), which alludes to the imprisonment of Naevius, an event which cannot be proved to be earlier than 206 B.C. The defects of construction and the absence of "can- tica" in the Miles also point to this as one of his early plays. On the other hand it is hardly likely that all his comedies (which greatly exceeded in number the extant twenty) were produced during the last twenty years of his life. Finscher assigns the Aulularia to a date as early as 212 B.C. Of the extant plays the Cistellaria and the Stichus must be associated with the Miles as comparatively early works; for the former was clearly produced before (though not long before) the conclusion of the Second Punic War, see l. 201 seq.; and the Stichus is proved by its didascalia to have been produced in 200 B.C. The Pseudolus and the Truculentus fall within the last seven years of his life. The dates of the rest of the extant plays, here given in alphabetical order, are quite uncertain, namely, Amphitruo, Aulularia, Bacchides, Captivi, Cosa, Curculio, Epidicus, Menamachmi, Mercator (probably a little later than the Rudens, as shown by F. Marx), Mostellaria, Persa, Poenulus, Rudens, Trinummus (later than 194 B.C.; cf. novi udeles in l. 990). Of the Vvidularia we possess only the fragments contained in the Codex Ambrosianus.

The plays of Plautus are all based on Greek originals.1 To what extent he is dependent on these originals, and how far he departed from them, we shall perhaps never know exactly. But such evidence as we have points to a pretty close imitation on the part of the Roman poet: there are passages in which he does not hesitate to take over from his originals allusions which can hardly have been intelligible to a Roman audience, e.g. the reference to Stratonicus, a musician of the time of Alexander the Great (Rudens, 93); and in the delineation of character we have no reason to suppose that he improved on his models (cf. Aul. Gell. ii. 23). Even the prologues, which later researches have shown to be in the main by the hand of Plautus himself, though certain passages were clearly added at a later date, e.g. Cas. prol. 5-20, may in most cases have formed part of the Greek original. Plautus must therefore be regarded as primarily a translator or adapter, so far as our present knowledge goes. Where he varies his plot on lines of his own by amalgamating the plots of two distinct Greek comedies (e.g. in the Miles and the Poenulus) the result is generally not happy; and the romanization of the plays by way of allusions to towns in Italy, to the streets, gates and markets of Rome, to Roman laws and the business of Roman lawyers, censors, comedies,ática, and of some passages (e.g. Poenulus, 620, 550).

1See further P. E. Legrand, Dass: tableau de la comédie grecque pendant la période dite nouvelle (1010).

Plautus was a general favourite in the days of republican Rome. Cicero, though he found fault with the imbecility of the Latin comedians generally as obiecti, "prosaic" (Orator, liv. 184), admired Plautus as elegans, urbanus, ingenuus, facetus (De offic. i. 29, 104). To the fastidious critics of the Augustan age, such as Horace, he seemed rude (cf. Ars Poetica, 270-274), just as Addison declared Spenser to be no longer fitted to please a cultivated age." In another passage (Epist. ii. 1, 170-176) Horace accuses him of clumsiness in the construction of his plays and the drawing of his characters, and indifference to everything excepting immediate success: gestit enim numnum in loculos demitere, post hoc securus cadat an recto set fabula talo. That there are many inconsistencies and signs of carelessness in his work has been proved in detail by Langen. But that he found many admirers, even in the Augustan age, Horace himself bears witness (ibid. l. 58), where he says that Plautus was regarded as a second Epicharmus: Plautus ad exemplar Siculi proponere Epicharmi—a passage which is important as suggesting that
Plautus was under some obligation to the Sicilian representatives of the old Dorian comedy; cf. Varro's statement (in Priscian ix. 32, deinde ad Siculos se appellavit). It is probable that Plautus may have been working on the lines of the old name which he is so fond of inventing for his characters, such as Polyxena-defodaglides (Pseud. 686), Pyrgopolinices (Mill. 56), Thensaurochrysonychises (Capt. 282) — names which stand in remarkable contrast to the more commonplace Greek names employed by Terence.

In the middle ages Plautus was little regarded, and twelve of his plays (Bacchides-Truculentus) disappeared from view until they were discovered (in the MS. called D) by Nicholas of Paris in the year 1429. Apparently some early archetype had been destroyed, and the latest which only the first (containing eight plays, Amphitruo- Epidicus) has ever claimed oblivion or destruction. After the revival of learning Plautus was reinstated, and took rank as one of the great dramatists of antiquity; cf. Polonius, Hamlet, i. i. 426, where Polonius says, "The best actors in the world . . . Seneca cannot be too heavy nor Plautus too light."

MANUSCRIPTS.—The chief MSS. of Plautus belong to two families, which are proved by the errors which they have in common to be descended from two ancient sources (Sicker, Novae quasitiones plautinae, in Philologia Latina, etc. vol. iii. (1882), i. 3). The representation (j), that represents the fragmentary palimpsest of the Ambrosian Library at Milan (A, 4th century a.d.), discovered in 1815 by Cardinal Mail and now accessible in several editions, by Seyffert (1886); (ii) that represented by the Palatine MSS. (P, 10th-16th centuries).</p>
PLAYA—Pleading

The primitive play instinct or play impulse in man has been much discussed in recent years by psychologists in connexion with child-

Plays (see child), and their function, and with the arts (see Art, the). See generally J. Sully, On Laughter, 1902, &c.; also Aesthetics. See generally C. G. Groos, The Play of Animals (1889) and The Play of Man (1901); and Baldwin's Dict. of Philosophy, s.v.

PLAYA (a Spanish word meaning "shore"), the name applied in America to a level plain formed of the deposits of a river which has no outlet to the sea or a lake. If at seasons of high water the wind blow across a plain and temporarily converts it into a

Lake, which subsequently dries up in hot weather, the tract this

Lake forms a playa. The barren Black Rock Desert in north-western Nevada, about 100 m. in length by 15 in breadth, is
typical.

PLAYFAIR, JOHN (1748-1819), Scottish mathematician and

Physician, was born at Benvie, Forfarshire, where his father was

Pastor, in 1746, when only eighteen, he was candidate

for the chair of mathematics in Marischal College, Aberdeen, and,

although he was unsuccessful, his claims were admitted to

Theological College, and he made application for the chair of

Natural Philosophy in his own university, but without success, and in 1773 he was offered and accepted the living of

The united parishes of Liff and Benvie, vacant by the death of

his father. He continued, however, to carry on his mathematical

and physical studies, and in 1782 he resigned his charge in order

to become the tutor of Ferguson of Raith. By this arrangement he was able to be frequently in Edinburgh, and to cultivate the literary and scientific society for which it was at that time

Specially distinguished; and through Maskelyne, whose acquaintance he had first made in the course of the celebrated Schiehallion experiments in 1774, he also gained access to the scientific circles of London. In 1785 when Dugald Stewart succeeded Ferguson in the Edinburgh chair of moral philosophy, Playfair succeeded the

former in that of mathematics. In 1782 he published his celebrated volume entitled Illustrations of the Huttonian Theory of the Earth. To its publication the influence exerted by James

Hutton on the progress of geological knowledge is largely due.

In 1805 he exchanged the chair of mathematics for that of

Natural Philosophy in succession to Dr John Robison, whom also he succeeded as general secretary to the Royal Society of Edinburgh. He took a prominent part, on the liberal side, in the ecclesiastical controversy which arose in connexion with Licensing Bills, and when he moved to the post he had vacated, and published a satirical Letter (1806) which was greatly admired by his friends. He was elected F.R.S. in 1807. He died in Edinburgh on the 20th of July 1819.

A collected edition of Playfair's works, with a memoir by James G. Playfair, appeared at Edinburgh in 4 vols. 8vo. His writings include a number of essays contributed to the Edinburgh Review from 1804 onwards in the Phil. Trans. (including his earliest publication, 'On the Arithmetic of Impossible Quantities,' 1779, and an 'Account of the Lithological Survey of Schiehallion,' 1811) and in the Transactions of the Royal Society of Edinburgh ('On the Causes which affect the Accuracy of Barometrical Measurements,' &c.), also the articles 'Apeinus' and 'Physical Astronomy,' and a 'Dissertation on the Progress of Mathematical and Physical Science since the Revival of Learning in Europe,' in the Encyclopædia Britannica (fourth, fifth and sixth editions). His Elements of Geometry first appeared in 1795 and have passed through many editions; its Outlines of Natural Philosophy (2 vols., 1812-1816) consist of the propositions and formulae which were the basis of his class lectures. Playfair's contributions to pure mathematics were not considerable, his paper 'On the Arithmetic of Impossible Quantities,' that on the Conversion of Barometrical Measurements,' and his Elements of Geometry, all related already to, being the most important. His Lives of Matthew Stewart, Hutton, Robison, many of his reviews, and above all his 'Dissertation' are of the utmost value.

PLAYFAIR, LYON PLAYFAIR, 1st BARON (1818-1888), was

born at Chunar, Bengal province, on the 21st of May 1818. He

was sent to Europe by his father at an early age, and received his first education at St Andrews. Subsequently he studied medicine at Glasgow and Edinburgh. A short visit to India (in 1837-1838) was followed by his return to Europe to study

chemistry, which had always attracted him. This he did at University College, London, and afterwards under Liebig at Giessen, where he took his doctor's degree. At Liebig's request, Playfair translated into English the former's work on the Chemistry of Agriculture, and represented Liebig at a meeting of the British Association at Glasgow. The outcome of his studies was his engagement in 1841 as chemical manager of the Primrose print-works at Clitheroe, a post which he held for rather more than a year. In 1843 he was elected honorary professor of chemistry to the Royal Institution of Manchester, and soon afterwards was appointed a member of the Royal Commission on the Health of Towns, a body whose investigations may be said to have laid the foundations of modern sanitation. In 1846 he was appointed chemist to the geological survey, and thenceforward was constantly employed by the public departments in matters of sanitary and chemical inspection. The opportunity of his life came with the 1851 Exhibition, of which he was one of the special commissioners. For his services in this connexion he was made C.B., and his work had the additional advantage of bringing him into close personal relations with the Prince Consort, who appointed him gentleman usher to his household. From 1856 to 1860 he was professor of chemistry at Edinburgh University. In 1868 he was elected to represent the universities of Edinburgh and St Andrews in parliament, and retained his seat till 1885, from which date until 1892 he sat as member for Leeds. In 1873 he was made postmaster-

general, and in the following year, after the dissolution of parliament, was applied to by the incoming Tory government to preside over a commission to inquire into the working of the civil service. Its report established a completely new system, which has ever since been officially known as the "Playfair scheme." The return of Mr Gladstone to power in 1880 afforded opportunity for Playfair to resume his interrupted parliamentary career, and from that time until 1893 he acted as chairman of departments during a period when the obstructive tactics of the Irish party were at their height. On his retirement from the post he was made K.C.B. In 1892 he was created Baron Playfair of St Andrews, and a little later was appointed lord-in-waiting to the queen. In 1895 he was given the G.C.B. In spite of failing health the last years of his life were full of activity, one of his latest public acts being his suggestion that Queen Victoria's Diamond Jubilee of 1897 should be commemorated by the completion of the South Kensington Museum. He died in London, after a short illness, on the 14th June 1898, and was buried at St Andrews. He was three times married. He was the author of a number of papers on scientific and social topics, a selection from which he published in 1889 under the title of Subjects of Social Welfare.

A memoir by Sir Wemyss Reid was published in 1899.

PLEADING (Fr. pléader, plaidoyer), the term applied in

English law to the preparation of the statement of the facts on

which either party to a criminal prosecution or a civil action

founds his claim to a decision in his favour on the questions

involved in the proceeding; and also to the document in which

these statements are embodied. The term "pleadings" is used for

the collected whole of the statements of both parties; the term "pleading" for each separate part of the pleadings. The term "plead" (plaid) is now applied in England oftener to

the defence made by an accused person. To "plead" is to make a pleading or plea. 2

All systems of law agree in making it necessary to bring the

grounds of a claim or defence before the court in a more or

less definite and technical form.

Roman System.—In Roman law the action passed through three

stages (see Action), and the manner of pleading changed with

the action. In the earliest historical period, that of the legis actions, the

pleadings were verbal, and made in court by the parties them-

selves, the proceedings imitating as far as possible the natural

1 In Scots and ecclesiastical law the word "plea" is used as to

the statements of both parties to a cause.

2 In French law plaider and plaideyer are still applied to the

oral arguments of counsel, and in English popular speech "to

plead" has much the same sense.
PLEADING

conduct of persons who had been disputing, but who suffered their quarrel to be appraised (Maine, Anciell Law, ch. x.). The use of technical language and pleading at nisi prius came to pass as a matter of course, and it must be borne in mind that, as Gains tells us, the party who made even the most trivial mistake would lose his suit. This excessive reverence for formality is a universal characteristic of archaic law. In the several systems of procedure, the formulae, the pleadings were used to express the technicalities of the law. In the case of the judea, the "fidei." The judea decided was made up by the proctor in writing from the statements of the parties, before him. The formula was a short summary of the facts in dispute in technical language, with instructions to the judea, and corresponded to what would now be called the submission or terms of reference to an arbitrator chosen by the parties. The part of the formula which contained the plaintiff's claim was called the "intentio." Any equitable defence, however, was introduced into the wording of the formula by means of an exceptio, which was either peremptory, denying the right of the plaintiff to recover at all, or dilatory, denying only that the action could be brought at the time, or by the particular plaintiff. The plaintiff might meet the exceptio by a repatiatio, the defendant on his side might set up a duplicatio, and the plaintiff might traverse the duplicatio by a triplicatio. The parties might proceed even further, but beyond this point the pleadings had no special names. Actions bona fide implied every exceptio that could be set up; in other actions the exceptio must be specially pleaded. From the formula the judea derived his whole authority, and he was liable to an action for exceeding it. He could not amend the formula; that could only be done by the proctor. In the third period the formula did not exist, the plaintiff's claim appeared in the summons (declaratio, or the declaration), but might take the form that he pleased, all actions being placed on the footing of actions bona fide. The issue to be tried was determined by the judge from the oral statements of the parties.

English System.—The English system of pleading seems to have drawn largely from, if it was not directly based upon, the Roman. Bracton (temp. Henry III.) uses many of the Roman technical terms. Pleading was oral as late as the reign of Henry III., and it is recorded that the law of pleading was only drawn up in writing, perhaps at first more for the purpose of entry on the court records than for the instruction of the court (see 2 Reeves, History of English Law, p. 308). The French language was used until 1362, after which English was used for oral pleading, but Latin for enrolment, except for a short period during the Commonwealth. Latin was the language of written pleadings at common law until 1731. The period of the Roman formula has its analogue in the period of the original writ in England.1 The writ was at first a formal commission from the Crown to a judicial officer to do justice between the parties, the claim being made by a count (comt, narratio). The issue of the plaintiff, and the preponderance of the case, was left to the Crown, which might decide whether the case was to be heard until the Provisions of Oxford (1258) forbade the issue of fresh writs except "writs of course" (de curso) without the consent of the council. Gradually the writ came to absorb the count and include the plaintiff's claim, and sometimes the nature of his evidence. The defendant pleaded to the writ. The writ became the universal form of instituting proceedings in the king's court, irrespective of the method of trial which followed, and probably grew fixed in form about the reign of Henry II. (see Bigelow, History of Procedure, ch. iv.). At a later date the writ again tended to approach its earlier form and to split into two parts—the writ of summons and the declaration or plaintiff's claim. The writ of summons was addressed to the defendant, and not, as the original writ, to a judicial officer. The pleadings became the set of the party, differing in this from Roman law, in which they were a judicial act. The writs became precedents for the forms of action, which, like the writs, were limited in number. The plaintiff's declaration was a substantial repetition of the writ. In the writ, as in the formula, the slightest failure in form was as a rule fatal. 2

1 The original writ was so called to distinguish it from the judicial writ, which was a part of the process of the court. The judicial writs still exist, e.g. writs of certiorari or fieri facias.

2 The ingenuity of the pleader showing itself chiefly in framing special as opposed to general pleas, the term "special pleading" grew to be used for the whole proceedings of which it was the most important part.

3 In Chancery the "English Bill," so called from its being in the English language, had existed, according to G. Spencer, as early as the reign of Henry V. (Equitable Jurisdiction, i. 348).

4 Bullen and Leake, Precedents of Pleading (3rd. ed., 1868).
forms or required special statement. The declaration conveys to the Roman formula and intension.

2. Plea by the defendant to the counts of the declaration. The plea conveys to the Roman exceptio.

3. Replection by the plaintiff to the plea. In this pleading the plaintiff usually took issue upon the statements in the defence; but he might do what was termed "new assign," e.g. complain of acts in excess of a justification alleged in the plea.

4. Demurrer by the defendant to the replection, answering to the Roman surrejoinder.

5. Surrejoinder by the plaintiff to the rejoinder, answering to the Roman tripartition.

6. Rebutter by the defendant to the surrejoinder.

7. Surrebutter by the plaintiff to the rebutter.

Nos. 4, 5, 6 and 7 were rarely necessary, as the parties usually carried on their ad hoc disputes through the factum,答辩, replication, and the last of them is only kept in legal memory by Lord Wensum (the last and best versed of the old common law pleaders) was nicknamed Chief Baron Surrebuttre. At any stage of the pleadings either (i) the party might instead of pleading to the preceding document demurr, i.e. admit the facts as therein stated and contend that any of the truth of those facts the document was insufficient in law to found a claim or a defence as the case might be. Demurrers (q.v.) were general or special according as they negated the substance of the claim or plea or to a mere defect in the mode of statement. When the pleadings had reached a stage at which the issues were in the contradiction on matters of fact, they concluded by joinder of issues upon which the record was made up and the action was ripe for trial.

Plea fell into the following classes—

1. Presentation of temporary or dilatory (terms of Roman law, directed either to the jurisdiction of the court or to the abatement or defeat of the action for defects of form.

2. In bar, also described as peremptory, which answered the allusion of the defendant to the pleadings and was directed to the pleadings, which were material, or by confessing their truth, but stating new matter of fact which destroyed their legal effect.

Some of these were by way of justification or excuse, e.g. by setting up the truth of matter alleged to be defamatory, or legal warrant for an arrest complained of as illegal: others were by way of discharge, e.g. of an alleged debt by payment.

Plead in denial were known (a) as general traverses or general issues. They were a general, and appropriate form one or more of the facts alleged (e.g. "never indebted " to a claim in assumpsit or " not guilty " to a claim for tort); (b) as specific traverses or special issues. They were a statement or declaration in the declaration, setting out with particularity the facts relied on.

It was permissible to plead alternatively, i.e. to set up a number of different answers to the facts on which the claim was based. As a general rule a plea must be "issuable," i.e. must put the merits of the case in issue on the facts or the law, so that the decision of judge and jury thereon would put an end to the action upon the merits.

All the above forms of pleading, except in matrimonial causes, were abolished by the Judicature Acts, and a new system was set up by these acts and the rules of the Supreme Court. Under this system the pleadings proper are "statement of claim," "defence," "reply," and, if need be, "rejoinder." There, pleadings will be described by the following, and contain only, in a statement in summary form of the material facts on which the party pleading relies for his claim or defence, as the case may be, but not the evidence by which they are to be proved; and must, when necessary, be divided into paragraphs, numbered consecutively.

Date, sums and numbers are expressed in figures and not in words. Signature of counsel is not necessary; but where pleadings have been settled by counsel or a special pleader they are to be signed by him, and if not so settled they are to be signed by the solicitor or by the party if he sues or defends in person (O. 19, r. 4). There has been a growing disposition to dispense with formal pleadings in the simpler kinds of action. A plaintiff is allowed to proceed to trial without pleadings if the writ of summons is endorsed in a manner sufficient to indicate the nature of his claim and the relief or remedy which he seeks (O. 18a), and contains a notice of his intention. In no case is a statement of claim other than that endorsed on the writ necessary unless the defendant on appearance asks for one, and his right to insist has been cut down by the provisions presently, to be stated. In commercial cases a statement by the parties to the points of law and fact which they propose to raise is substituted for ordinary pleadings. In cases where the demand is for a liquidated sum certain, or to recover land from a tenant on expiration of his term or its forfeiture for non-payment of rent, the statement of claim must be endorsed on the writ; and in all other cases no statement of claim beyond the form of the writ may be delivered except under order of the master or judge at Chambers (O. 30). A statement of defence may not be delivered except under order of the master or judge or the justices summons for directions (which must be taken out immediately after the appearance of the defendant in answer to the writ), nor a reply without special leave. The result of the present practice is to substitute "particulars," i.e. specific statement of the details which the parties intend to prove, for the more general terms in which pleadings were formerly framed.

Besides the rules applicable to all pleadings, there are certain rules specially relating to statements of claim, with reference to the nature of the causes of action which are included and the procedure by which may be claimed (O. 20). As to the defence proper, there are also special rules intended to prevent evasive, inadequate or unnecessary contradiction of the plaintiff's statements (O. 19, 20). The defendant is allowed to "set off" against the claim, due to him from the plaintiff or to raise by way of counter-claim any right or claim against the plaintiff or a third party, whether it be on account of damages or otherwise. The counter-claim is in substance a conjoined action in which the defendant, or a defendant or third party affected may put in a defence to it. Except in such a case the reply and subsequent pleadings are now seldom permitted, though in some cases and for some purposes the defendant may amend the pleadings both before and at the trial. Issues are in certain cases settled by the court or a judge. Demurrers are abolished, and a party is now entitled to raise by his pleading all matters of fact and law which are necessary to the end to the action steps may be taken for obtaining such decision so as to obviate the necessity of trying the issues of fact raised on the pleadings. Forms of pleading are given in Appendices C and D. The Supreme Court Rules. In all actions such power of defence or reply as if not raised would be likely to take the opposite party by surprise, or would raise issues of fact not arising out of the pleadings, must be specially pleaded. Such are compulsory pleadings from the Statute of Limitations, the Statute of Frauds and the Gaming Act. The Supreme Court Rules do not apply to proceedings in Crown suits or in the Crown Court. The Court of Appeal (C. 36, r. 39) has power to make an order to quash a decision of the district judge and of the officer entering the judgment (O. 36, r. 39; O. 41, r. 1).

In the county courts proceedings are commenced by a plaint, followed by an ordinary or default summons. No "pleadings" are necessary here except in certain special cases, the trial up certain special defences such as set-off or infancy, or statutory defences, without the consent of the plaintiff, unless he has given timely notice in writing of his intention to set up the special defence. This system is made workable by insisting on the insertion of adequate details or particulars of the nature of the claim in the plaint. But in cases where a special defence is not required considerable inconvenience is caused by uncertainty as to the line of defence.

In some of the local civil courts of record which have survived the creation of the county courts, the pleadings are still in form recognized by the Common Law, and the Act (the case in the Supreme Court of London). In others (e.g. the Liverpool Court of Passage and the Salford Hundred Court) the system of the Judicature Acts is adopted without any change. The policy of the lord chancellor and the treasury has been to refuse reform of procedure to all but the most used of these local courts so as to extinguish them in favour of the county courts. These civil cases are called generally pleas. The statement of the plaintiff in civil suits is called a libel; of the promoter in criminal suits articles. Every subsequent plea is called an allegation. The burden of proof is on the plaintiff. The defendant may plead a counter-allegation. The cause is concluded when the parties renounce any further allegation. There exists in addition a more short and summary mode of pleading called an act on petition.

In Roman criminal procedure the indictment (inscriptio or...
PLEASURE—PLEBS

Libellus (accusationis) was usually in writing, and contained a formal statement of the offence. In some cases oral accusations were allowed. The pleading of the accused seems to have been informal. In English criminal cases the expression "pleadings" is limited to those tried on indictment or information before a jury. In matters dealt with by justices of the peace there are informations sometimes in writing, but they are never regarded as "pleadings." English criminal pleading has been less affected by legislation than civil pleading, and retains more of what is called the common law system. Cases in which the Crown was a party early became known as "pleas of the Crown" (placita coronae), as distinguished from "common pleas" (communia placiala), or pleas between subject and subject—that is to say, ordinary civil actions. Pleas of the Crown originally included all matters in which the Crown was concerned, such as exchequer cases, franchises and liberties, but gradually became confined to criminal matters, strictly to the greater crimes triable only in the king's courts. In criminal pleading the Crown states the case in an indictment or information. The answer of the accused is a plea, which must be pleaded by the accused in person, or his legal representative. When the accused pleads in person, the process is called a personal plea; if by his agent, the plea is deemed a representative plea by Blackstone, and still further by Blackstone's successors (see PLEADER). The plea of atrofésis convict or atrofésis acquit (alleging a previous conviction or acquittal for the same crime) and pardon (see PARDON). The plea of atrofésis altātum has fallen out of use since the abolition of attainder by the Forfeitures Act 1870. There are also special pleas of justification to indictments for defamation libel under the Libel Act 1843; and to indictments for non-repair of highways and bridges the accused may plead that the liability to repair falls upon another person. These special pleas are usually, and in some cases must be, in writing. When there is a special plea in writing the Crown puts in a reply, also in writing.

Ireland.—The practice as to civil and criminal pleading in Ireland is substantially the same as in England, though to some extent based on different statutes and rules of court.

Scotland.—In Scotland an action in the Court of Session begins by a summons on the part of the pursuer, to which is annexed a concensuence, containing the plea. The plea is either "in law" or "in fact," as in Roman law. If it be in law, it is made as a general term to express the claim of the pursuer or the accusation of the prosecutor. The statement of the defender, including his plea in law, is called his defences. They are either personal or general. The personal defences have the nature of a plea in law as in England, but the same end is attained by adjustment of the pleadings and the closing of the record. Large powers of amendment and revision are given by the Court of Session Act 1868. In the sheriff court pleadings are similar to those in the Court of Session. They are commenced by a petition, which includes a concensuence and a note of the pursuer's plea in law. The defender may upon notice lodge defences. The procedure is now governed by the Sheriff Courts (Criminal Procedure) Act 1871. The "pleas of the Crown" is confined in Scotland to four offences—murder, rape, robbery and fire-raising. The criminal procedure of Scotland was reformed and amended in 1870. The old procedure by criminal licenses has been abolished and prosecutions for the public interest whether in the high court of justiciary or before the sheriff with a jury are by indictment in the name of His Majesty. The Scots introduced English in not being found by a grand jury, except in cases of high treason and resembles rather the ex officio information of English law. Until 1887 it was in the form of a syllogism, the major proposition stating the nature of the crime, the facts in which the defendant was charged and that it constitutes the crime named in the major, the conclusion that on conviction of the panel he ought to suffer punishment. Under the present practice it is in the second person and follows the action and is of the form of the late 17th century. The issues are made in the act of 1887, which also makes specific provisions for simplification, and if need be for amendment (s. 70). A copy of the indictment with a list of the witnesses and the productions must be served on the accused. There is no grand jury. The first diet is the first pleading. At the first diet, before the sheriff, the accused (termed the panel) may plead guilty or raise preliminary objections to the relevancy of the indictment, &c., or otherwise (such as want of pecuniary means, &c.) to the defences not being taken. If after they are overruled, may plead not guilty. The second diet is the diet of trial. If the trial is before the sheriff his rulings at the first diet are final, if before the court of justiciary his judgments may be reviewed. At the second diet, besides his plea of not guilty, the panel may rely on certain special defences, e.g., insanity or alibi, but only if his special and written plea was tendered and his defence not in evidence, and in either case a new case must be made. The evidence in support of these pleas except on written notice specifying the names of the witnesses and the documents not included in the prosecutor's lists (s. 36). (See Macdonald, Criminal Law of Scotland.)

British Dominions Beyond Seas.—In most of the Australian states, and in Ontario and New Zealand, civil pleadings are governed by rules adopted from the English Judicature Acts. In New South Wales a system based on the English Common Law Procedure Act is retained. Civil pleadings in India are regulated by the Civil Procedure Code. Indictments, except in India, are based on the common law system as modified by the Criminal Code of 1852, or on other legislation of the colony. In India are regulated by the Criminal Procedure Code of 1898.

United States.—In the United States two systems of pleading in civil procedure exist, either side by side. Up to 1870 the pleading did not materially differ from that in use in England at the same date. But in 1848 the New York legislature made a radical change in the system, and the example of New York has been followed by many states. The New York Civil Code of 1848 established a uniform procedure called the civil action, applicable indifferently to common law and equity. The pleadings are called complaint, answer (which includes counterclaim) and reply. The defences also are still used, but in some states which allow this procedure are retained. Civil pleadings in other states are based on the common law system, and are often not distinguishable from those in England. In inferior courts, such as courts of justices of the peace, the pleadings are more simple, and in many cases oral. In states which do not adopt the amended procedure the pleading is much the same as it was in the old system of Blackstone, and the old double jurisdiction of common law and equity still remains. Criminal pleading is on the lines of the common law system of England.

PLEASURE (through Fr. plaisir from Lat. placere, to please; Gr. ἱδρον), a term used loosely in ordinary language as practically synonymous with "enjoyment." As such it is applied equally to what are known as the "higher" or "intellectual" pleasures, e.g., the "love of beauty" (or of truth), or "a philosophy of life," and in cases of this character is used in writing. The conditions under which a man is pleased are the subject both of psychological and of ethical investigation. In general it may be said that pleasure and pain follow respectively upon the success of the failure of some effort, mental or physical (see PSYCHOLOGY); they may also attend upon purely passive sensations, e.g., a warm sun, a heavy shower, or upon associations with previous states of mind (i.e., a man may enjoy a sensation which is intrinsically painful, if it has pleasant associations). Recognition of the fact that mankind seeks pleasure and avoids pain has led some moralists to the conclusion that all human conduct is actuated by hedonic considerations: this is the direct antithesis of the theory of the Good or of the aesthetic theory which affirms that the "right" conduct is that which is in accordance with some universal moral law (see HEDONISM; ETHICS). Aristotle took a middle view, holding that pleasure, though not the end of virtuous action yet necessarily follows upon it (ἐντονομωμένοι τι τέλος).

Plebsicite (Lat. plebscitum, a decree of the plebs), a term borrowed from the French for a vote of all the electors in a country taken on some specific question (see also REFERENDUM). The most familiar example of the use of the plebsicite in French history was in 1852, when the coup d'état of 1851 was confirmed and the title of emperor was given to Napoleon III. In Roman constitutional law the plebscicite was a decree enacted in the assembly of the plebs, the comitia tributa, presided over by a plebeian magistrate. The plebs, from the root seen in Lat. plenus, full; cf. Gr. πλήρος, "the multitude," or unprivileged class in the early Roman state. For the origin and history of this order see PATRICIANS and NOBILITY. Its disqualifications were originally based on
PLEDGE—PLEISTOCENE

Pledge, or Pawn, in law “a bailment of personal property as a security for some debt or engagement” (Story on Bailments, § 286). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law, from which most of the modern law on the subject is derived. It differs from hypothec and from the more usual kind of mortgage in that the pledge is in the possession of the pledger; it also differs from mortgage in being confined to personal property. A mortgage of personal property in most cases takes the name and form of a bill of sale. The chief difference between Roman and English law is that certain things, e.g., wearing apparel, furniture, and instruments of tillage, could not be pledged in Roman law, while there is no such restriction in English law.

In the case of a pledge, a special property passes to the pledger, sufficient to enable him to maintain an action against a wrongdoer, but the general property, that is the property subject to the pledge, remains in the pledger. As the pledge is for the benefit of both parties, the pledge is bound to exercise only ordinary care over the pledge. The pledger has the right of selling the pledge if the pledger make default in payment at the stipulated time. No right is acquired by the wrongful sale of a pledge except in the case of property passing by delivery, such as money or negotiable securities. In the case of a wrongful sale by a pledger, the pledger cannot recover the value of the pledge, unless the pledger gives a tender of the amount due.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and in Louisiana a pledge cannot be sold unless with judicial authority. In some of the American states the common law as it existed at the start of the Factors' Acts is still followed; in others the factor has more or less restricted power to give a title by pledge.

See also Factor and Pawnbroking.

Pleihe, Viatcheslas Konstantinovich (1846–1904), Russian statesman, was born of Lithuanian stock in 1846. He was educated at Warsaw and studied law at the university in St. Petersburg before he entered the bureaucracy in the department of justice, in which he rose rapidly to be assistant solicitor-general in Warsaw, then solicitor-general in St. Petersburg, and in 1881 director of the state police. As assistant to the minister of the interior he attracted the attention of Alexander III. by the skill he showed in investigating the circumstances of the assassination of Alexander II. He received the title of secretary of state in 1894, became a member of the council of the empire, and in 1902 succeeded Sisipagime as minister of the interior. Pleihe carried out the “russification” of the alien provinces within the Russian Empire, and earned bitter hatred in Poland, in Lithuania, and especially in Finland. He despised the Armenian Church, and was credited with being accessory to the Kishinev massacres. His logical mind and determined support of the autocratic principle gained the tsar’s entire confidence. He opposed commercial development on ordinary European lines on the ground that it involved the existence both of a dangerous proletariat and of a prosperous middle class equally inimical to autocracy. He was thus a determined opponent of M. de Witte’s policy. An attempt was made on his life early in 1904, and he was assassinated on the 28th of July of the same year by a bomb thrown under his carriage as he was on his way to Peterhof to make his report to the tsar. The assassin, Sasnov, was a member of the fighting organization of the socialist revolutionists.

Pleiad (Gr. Πλεῖάδ), in Greek literature, the name given (by analogy from Pledes, below) by the Alexandrian critics to seven tragic poets who flourished during the reign of Ptolemy I. The word “pledge” is adapted from the O. Fr. *plege*, mod. *pledge*, security, hostage, Med. Lat. *plevium*. This is a formation from Med. Lat. *plevere* or *plebire*, to undertake or engage for someone, cf. *pledge*. It is a word of Teutonic origin and connected with Ger. *pflegen* and “plight.”

Philelphus (285–247 B.C.). In French literature, in addition to the Pleiad of Charlemagne, there were two famous groups of the kind. The first, during the reign of Henri III. (1574–1589), the chief member of which was Pierre de Ronsard, sought to improve the French language and literature by enthusiastic imitation of the classics; the second, under Louis XIII. (1601–1643), consisted of authors who excelled in the composition of Latin verse.

Pleiades, in Greek mythology, the seven daughters of Atlas and Pleione, and sisters of the Hyades. Owing to their grief at the death of their sisters or at the sufferings of their father, they were changed into stars. In another account, the Pleiades and their mother met the hunter Orion in Bocotia, and the sight of them inflamed his passion. For five years he pursued them through the woods, until Zeus translated them all—Pleione and her daughters, Orion, and his dog—to the sky. The Pleiades rose in the middle of May and set at the end of October, and their connexion with spring and autumn explains the legend. As bringers of the fertilizing rains of spring, which have their origin in the west, they are the daughters of Atlas; as the forerunners of the storms of autumn, they are represented as being driven onward by Orion in pursuit. The word is probably connected with *πλεῖν*, either in the sense of “many in number,” since the stars formed a close group, resembling a bunch of grapes (hence sometimes called *βόρεια*), or as “more in number” than their sisters. Others derive the name from *πλείω* (to sail), because navigation began at the time of their rising. They are probably alluded to in Homer (Odyssey, xii. 65) as the doves (*πλειάδες*) who brought ambrosia from the west to Zeus. One of these doves was always lost during the passage of the *Planctae* (wandering rocks), referring to the fact that one of the seven Pleiades was always invisible. This was Merope, who hid her light from shame at having had intercourse with a mortal, Sisyphus. All the Pleiades became the ancestresses of divine or heroic families. They were called Vergiliani (probably connected with *ver*, spring) by the Romans.

See Hesiod, Works and Days, 382; Apollodoros iii. 10; Diod. Sic. ii. 67; Theophrastos xii. 23; Hyginus, Astronom. ii. 217; Ovid, Fasti, iv. 159, v. 597.

Pleiades, Atlantides or Vergiliani, in astronomy, a group of stars situated in the constellation Taurus. They are supposed to be referred to in the Old Testament (Job. ix. 9, xxxviii. 31). This group is particularly rich in bright stars, and is full of nebulousity, but there are fewer faint stars than in equal areas of the surrounding sky; the central star is Alecto (3rd magnitude); Pleione and Atlas are also of the 3rd magnitude.

Pleistocene, in geology, the epoch which succeeded the Pliocene; it is the last of the Tertiary periods, and hence the lower subdivision of the quaternary or modern era. The name was introduced by Sir C. Lyell in 1839 (from Gr. *πλεῖστος*, most, and *καιων*, recent); the rocks of this period containing a higher percentage of living forms than the youngest of the Tertiary formations. By many writers “Pleistocene” has been regarded as synonymous with “Glacial Period” or the “Diluvium” of some geologists. In the northern hemisphere the protracted period of glaciation, with its predominating influence upon modern topography and faunal distribution, was undoubtedly the outstanding feature of the time. The phenomena of the Glacial period (*q.v*), which was by no means strictly limited to the northern latitudes, are dealt with under that head, but there are certain other characteristics of the Pleistocene period which bear no direct relationship to glaciation, and these will be dealt with here.

The gradual inception of colder conditions in the northern hemisphere, which led up to the more extreme conditions of glaciation clearly began in the latter part of the Pliocene period, and the effects of this cooling are seen not only in northern Europe and America but as far south as the Mediterranean. The result of this is that there is a certain indefiniteness as to the exact base line to be adopted for the Pleistocene formations; thus the Forest Bed of Cromer and certain beds in Sicily and Italy are by some authors placed in this period and by others
PLEONASM—PLESIOSAURUS

in the Pliocene (q.v.). Again it is clear that in parts of northern Europe, Siberia and North America, the conditions characteristic of a glacial period are still existent; even in Scotland and Norway the last traces of glacial action are remarkably fresh, and the last remnants of great glacial centres still linger in the Alps and other lofty southern mountains. Many of the formations of this period can be shown by their fossil contents to belong to early quaternary time, but since so many of these deposits are arctic in character, and the fact that some are present in any one spot have been determined by local geographical conditions which have assisted or retarded the migration of certain forms, it is a matter of extreme difficulty— one may say impossibility—to reduce the Pleistocene formations to any generally applicable chronological order. For similar reasons it is impossible to define strictly the upper limit of the formations of this period, and to say where the Pleistocene ends and where the Recent or Holocene period begins.

The composition and distribution of the Pleistocene fauna and flora present many points of extreme interest. The feature of greatest importance is that man existed somewhere and in some condition before and in this period; but no really satisfactory proof has so far been forthcoming which will set back his first appearance to the glacial period (Pleistocene), as the eurex found by E. Dubois in Java is regarded as of Pleistocene age.

The presence of the remains of man or of his works might reasonably be taken as a criterion of the Pleistocene age of a deposit— if we except the few cases where man has been here and there be born in mind that historical time is continually being set back by archaeological research, and further, the difficulty of employing arches of stone as chronological indicators is shown by the fact that in some cases the same period and stratigraphical formation and that different local races of early men must have been in diverse stages of development in Pleistocene as in later ages. It is, therefore, only with the utmost caution that chronological subdivisions of the period, such as those mentioned below, based upon the form and degree of finish of stone implements, can be used in anything but local correlations unless the evidence is supported by palaeontological fossils.

Next to the appearance of man the most striking characteristic of the land fauna was the existence of numerous large-bodied mammals; Elephas antiquus, for instance, attained a more excessive bulk than any other Pleistocene mammal either before or since; the woolly rhinoceros, the great hippopotamus, the cave bear, cave lion and giant deer were all larger than their living representatives. No less striking is the disappearance of these large forms together with highly specialized creatures such as Megaceros, and through the same period, by the action of the same causes which had re- moved the bulky and specialized reptiles of an earlier geological period. The evolution of the Pleistocene fauna into their characters has been borne in mind that historical time is continually being set back by archaeological research, and further, the difficulty of employing arches of stone as chronological indicators is shown by the fact that in some cases the same period and stratigraphical formation and that different local races of early men must have been in diverse stages of development in Pleistocene as in later ages. of Indian rivers. The neck, though long and slender, must have been rather stiff, because the bodies of the vertebrae are nearly flat-ended, while they bear short ribs: it could not have been bent in the swan-fashion represented in many restorations. The other vertebrae are also nearly flat-ended and firmly united, but there is no sacrum. The ribs are single-headed, and in the middle of the trunk, between the supports of the paired limbs, they meet a dense plastron of abdominal ribs. The short tail is straight and rapidly tapering, but one specimen in Berlin suggests that it was provided with a rhomboidal flap of skin in a vertical plane. The bones in the ventral wall of the body which support the paired limbs are remarkably expanded, and those of the pectoral arch have often been compared with the corresponding bones of turtles. The limbs are elongated paddles, with five complete digits, of which the constituent bones (phalanges) are unusually numerous. The only traces of skin hitherto discovered suggest that it was smooth. The reptile must have been almost exclusively aquatic, feeding on cuttlefishes, fishes and other animal prey. It propelled itself chiefly by the paddles, scarcely by the tail.

The typical species is *Plesiosaurus dolichodeirus*, from the Lower Lias of Lyme Regis, which attains a length of about three metres. Other species from the same formation seem to have measured five to six metres in length, and there are species of allied genera from the Upper Lias which are probably still larger. A fine large skeleton from the Upper Lias of Württemberg, now in the Berlin Museum, is named *Plesiosaurus gueldenstaedtii* (see figure above). *Cryptodira*, known by complete skeletons from the Oxford Clay of Peterborough, differs very little from *Plesiosaurus*. The Cretaceous *Cimoliosaurus*, found in North and South America, Europe and New Zealand, is also very similar. The fossilized contents of the stomach in some of the later *Plesiosaurus* show that these reptiles swallowed stones for digestive purposes like the existing crocodiles.

Owen, *Pliosaurus dolichodeirus* (Gr.), *Cimoliosaurus*, *Plesiophodon*, *Plesiophodon* (see figure above). *Cryptodira*, known by complete skeletons from the Oxford Clay of Peterborough, differs very little from *Plesiosaurus*. The Cretaceous *Cimoliosaurus*, found in North and South America, Europe and New Zealand, is also very similar. The fossilized contents of the stomach in some of the later *Plesiosaurus* show that these reptiles swallowed stones for digestive purposes like the existing crocodiles.

**PLEURISY** (Gr. πλεῦρα = ribs), inflammation of the pleura, caused by invasion of certain specific microorganisms. (See RESPIRATORY SYSTEM: Pathology.) Secondary pleurisies may occur from extension of inflammation from neighbouring organs.

The morbid changes which the pleura undergoes when inflated consist of three chief conditions or stages of progress. (1) Inflammatory congestion and infiltration of the pleura, which may spread to the tissues of the lung on the one hand, and to those of the chest wall on the other. (2) Exudation of lymph on the pleural surfaces. This lymph is of variable constitution, sometimes composed of thin and easily separated pellets, or of extensive thick masses or strata, or again showing itself in the form of a tough membrane. It is of greyish-yellow colour, and microscopically consists mainly of coagulated fibrin along with epithelial cells and red and white blood corpuscles. Its presence causes thickening of the two pleural surfaces, which, slightly separated in health, may now be brought into contact by bands of lymph extending between them. These bands may break up or may become organized by the development of new blood vessels, and adhering permanently may obliterating throughout a greater or less space the pleural sac, and interfere to some extent with the free play of the lungs. (3) Effusion of fluid into the pleural cavity. This fluid may vary in its characters.

The chief varieties of pleurisy are classified according to the nature of the effusion, whether it is serous or one of the other forms of fluid. There is a certain degree, however, of overlapping between the different types.

1. Serous pleurisy.
   - Pleural fluid thick and blood-stained, caused by: (a) Heart failure; (b) Pericarditis; (c) Rheumatism; (d) Hyperpyrexia; (e) Tuberculosis; (f) Consumption.

2. Effusion of a serosanguineous fluid.
   - Pleural fluid is at times thick and blood-stained, or absorbed from the circulation, as seen in: (a) Pericarditis; (b) Pleurisy; (c) Tuberculosis; (d) Rheumatic affection of pleura; (e) Consumption.

3. Effusion of a purulent fluid.
   - Pleural fluid is of a purulent nature, seen in: (a) Tuberculosis; (b) Pleuritis; (c) Empyema; (d) Pleurisy.

4. Effusion of a hydropurulent fluid.
   - Pleural fluid of a purulent nature, which becomes absorbed from the circulation, seen in: (a) Tuberculosis; (b) Pleurisy; (c) Empyema.

5. Effusion of a fibrous or plastic fluid.
   - Pleural fluid of a fibrous or plastic nature, seen in: (a) Tuberculosis; (b) Pleurisy; (c) Empyema.

6. Effusion of a phlegmonous fluid.
   - Pleural fluid of a phlegmonous nature, seen in: (a) Tuberculosis; (b) Pleurisy; (c) Empyema.

The absorption or removal of the fluid is marked by the disappearance or diminution of the above-mentioned physical signs, except that of percussion dullness, which may last a long time, and is probably due in part to the thickened pleura. Friction may again be heard as the fluid passes away and the two pleural surfaces come together. The displaced organs are repositioned and the compressed lung re-expanded. In such cases the effusion is often terminal.

In most instances the termination is favorable, the acute symptoms subsiding and the fluid (if not drawn off) becoming absorbed, sometimes after reaccumulation. On the other hand it may remain long without undergoing much change, and thus a condition of chronic pleurisy becomes established.
PLEURO-PNEUMONIA—PLEVNA

ordinary acute symptoms never having been present in any marked degree. Cases of this sort are often protracted, and their results unsatisfactory as regards complete recovery. In the treatment of early pleurisy, pain may be relieved by a hypodermic of morphia or the application of leeches. A purgative is essential. Fixation of the affected side of the thorax by strapping with adhesive plaster gives great relief. The ice-bag is useful in the early stages, as in pneumonia. The open-air treatment of cases is recommended, as the majority of the cases are of tuberculous origin. When effusion has taken place, counter irritation and the exhibition of iodide of potassium are useful. Dry diet and saline purgatives have been well spoken of. The most satisfactory method of treatment is early and if necessary repeated aspiration of the fluid. The operation (thoracentesis) was practised by ancient physicians, but was revived in modern times by Armand Trouseau (1801-1867) in France and Henry I. Bowditch (1860-1892) in America; by the latter an excellent instrument was devised for emptying the chest, which, however, has been displaced in practice by the still more convenient aspirator. The chest is punctured in the lateral or posterior regions, and in most cases the greater portion or all of the fluid may be safely drawn out. In many instances not only is the removal of distressing symptoms speedy and complete, but the lung is relieved from pressure in time to enable it to resume its normal function.

In cases of chronic pleurisy after the failure of repeated aspirations, Samuel West reports well of free incision and drainage. He has reported cases of recovery of fifteen, or eighteen months standing. Sir James Barr has advocated the treatment of these cases by the withdrawal of the fluid and the substitution of sterilized air and solution of supra-renal extract; others have introduced physiological salt solution or formalin solution into the cavity, after the removal of the fluid. Vaquez injected into the cavity and reports a number of cases in which it prevented recurrence.

PLEURO-PNEUMONIA, or LUNG-PLAGUE, a contagious disease peculiar to cattle, generally affecting the lungs and the lining membrane of the chest, producing a particular form of lobar or lobular pleuro-pneumonia, and, in the majority of cases, transmitted by the living diseased animal, or, exceptionally, by mediate contagion. It cannot be communicated to animals other than those of the bovine race. Inoculation of healthy cattle with the fluid from the diseased lungs produces, after a certain interval, characteristic changes at the seat of inoculation, and though it does not develop the lung lesions always observed in natural infection, yet there is a local anatomical similarity or identity. Though numerous investigations have been made, the nature of the infective agent remains doubtful. In 1888 Arlong, of Lyons, described various bacilli obtained from the lesions, but the pathogenic organism of lung-plague has not been discovered.

The earliest notices of this disease testify that it first prevailed in central Europe, and in the 15th century it was present in certain parts of southern Germany, Switzerland and France, and had also appeared in upper Italy. Though Valentine described an epizooty occurring among cattle in 1603 in Hesse, doubts have been entertained as to whether it was this malady. It was not until 1760 that it was definitely described as prevailing in France-Comté by the name of "marine." From that date down to 1789 it appears to have remained more or less limited to the Swiss mountains, the Jura, Dauphiné and Voges, Piedmont and upper Silesia; it showed itself in Champagne and Bourbonsais about the time of the Revolution, when its spread was greatly accelerated by the wars that followed. In the 19th century its diffusion was accurately determined. It invaded Prussia in 1802, and soon spread over north Germany. It was first described as existing in Russia in 1824; it reached Belgium in 1827, Holland in 1833, the United Kingdom in 1841, Sweden in 1847, Denmark in 1848, Finland in 1859, South Africa in 1854, the United States—Brooklyn in 1843, New Jersey in 1847, Brooklyn again in 1850 and Boston in 1850; it was also carried to Melbourne in 1858, and to New South Wales in 1866; New Zealand and Tasmania received it in 1864, but it was eradicated in both countries by the sanitary measures adopted. It was carried to Asia Minor, and made its presence felt at Damascus. It prevails in various parts of China, India, Africa and Australia, and until quite recently it existed in every country in Europe, except Scandinavia, Holland, Spain and Portugal. In Great Britain cases occurred in 1867.

Symptoms.—The malady lasts from two to three weeks to as many months, the chief symptoms being fever, diminished appetite, a short cough of a peculiar and pathognomonic character, with quickened breathing and pulse, and physical indications of lung and chest disease. Towards the end there is great debility and emaciation, death generally ensuing after hectic fever has set in. Complete recovery is rare.

The pathological changes are generally limited to the chest and its contents, and consist in a peculiar marbled-like appearance of the lungs on section, and fibrinous deposits on the pleural membrane, with oftentimes great effusion into the cavity of the thorax.

Williams of Hasselt (Belgium) in 1852 introduced and practised inoculation as a protective measure for this scourge, employing for this purpose the serum obtained from diseased lung. Since that time inoculation has been extensively adopted, not only in Europe, but also in Australia and South Africa, and its protective value has been generally recognized. When properly performed, and when certain precautions are adopted, it would appear to confer temporary immunity from the disease. The usual seat of inoculation is the extremity of the tail, the virus being introduced beneath the skin by means of a syringe or a worsted thread impregnated with the lymph. Protection against infection can also be secured by subcutaneous or intravenous injection of a culture of Arlong’s pneumo-bacillus on Martin’s bouillon, and by intravenous injection of the lymph from a diseased lung, or from a subcutaneous lesion produced in a calf by subcutaneous inoculation.

PLEVNA (Bulgarian Pleven), the chief town of the department of Plevna, Bulgaria; 85 m. N.E. of Sofia, on the Tutchinitza, an affluent of Vid, which flows north into the Danube and on the Sofia-Varna railway (opened in 1890). Pop. (1906), 21,268. A branch line, 25 m. long, connects Plevna with Samovit on the Danube, where a port has been formed. After the events of 1877, it was almost entirely forsaken by the Turks, and most of the mosques have gone to ruin; but, peopleed now mainly by Bulgarians, it has quite recovered its prosperity, and has a large commerce in cattle and wine.

Battles of 1877.—Plevna, prior to the Russo-Turkish War of 1877 (see Russo-Turkish Wars) a small and unknown town without fortifications became celebrated throughout the world as the scene of Osman Pasha’s victories and his five months’ defence of the entrenched camp which he constructed around the town, a defence which upset the Russians’ plans and induced them to devote their whole energies to its capture. Osman Pasha left Widin on the 13th of July with a column consisting of 19 battalions, 6 squadrons and 9 batteries, a total of 12,000 men and 54 guns. Hearing that he was too late to relieve Nikopol, he pushed on to Plevna, where there was a garrison of 3 battalions and 4 guns, under Atouf Pasha.

Passing through Plevna on the afternoon of the 19th of July he once took up a position, previously selected by Atouf Pasha, on the hills covering the town to the north and east. The column had been joined en route by 3 battalions from the banks of the Danube, so that Osman’s command now consisted of 25 battalions. He was none too soon. General Schilder-Schulzard, commanding the 5th division of the IX. corps, which had just captured Nikopol, had been ordered to occupy Plevna, and his guns were already in action. The Turkish batteries came into action as soon as they arrived and returned the fire. A desultory artillery duel was carried on till nightfall, but no attack was made by the Russians on the 19th. Osman distributed his troops in three sections: on the Janik Bair, facing north, were 13 battalions and 4 batteries, with advanced posts of 2 battalions
and 1 battery each, at Opanetz and Bukova, facing east and north-east, 5 battalions and 10 guns were posted on the eastern end of the Janik Bair; to the hills south of the Bulgareni road 4 battalions and 2 batteries were allotted, and on either side of the road, under cover, in rear of them, most of the cavalry was placed. The remaining troops formed a general reserve, which was posted on the hill just east of the town. The hills to the north and east of Plevna were perfectly bare. The Turks had covered the 115 m. from Widin in seven days, in trying heat, and were exhausted, but a few trenches were thrown up.

On the 20th of July at 5 a.m., having made no preliminary reconnaissance, the Russian commander brought his guns into action, and, after a short bombardment, advanced his infantry in four separate columns. On the north flank they pressed into Bukova, and also succeeded in driving back the Turkish right wing; but in both cases Turkish reinforcements arrived and with vigorous counter-attacks pressed back the Russians, with the result that by noon they were in full retreat, having lost 2800 men out of a total of 8000. The Turks lost 2000.

Osman made no attempt to reap the fruits of his victory by pursuit. He at once drew up plans for the fortification of the position, and the troops were employed night and day constructing redoubts and entrenchments. A plentiful supply of tools and daily convoys of stores reached Plevna from Orchanie, and on the 24th of July Osman's strength was increased by 14 battalions and a battery from Sofia. In order to secure his line of communications, on the 25th of July he sent a force of 6 battalions and 1 battery under Rifaat Pasha to occupy Lovcha (Lovats), where they entrenched themselves.

The Plevna garrison now numbered 20,000 (35 battalions, 8 squadrons, 57 guns and 400 mounted irregulars), who were organized in two wings with a general reserve. Adil Pasha commanded the left wing consisting of 12 battalions, 3 batteries and 2 squadrons, and held the ground from the Vid bridge to Grivitza; Hassan Sabri Pasha commanded the right wing, of equal strength, covering from Grivitza to the south. The remainder, as general reserve, was posted on the crest and slopes of the hill east of the town, with one battalion in Plevna itself. The west front was not fortified till October. Trenches were

The Turks lost 2000.

Osman made no attempt to reap the fruits of his victory by pursuit. He at once drew up plans for the fortification of the position, and the troops were employed night and day constructing redoubts and entrenchments. A plentiful supply of tools and daily convoys of stores reached Plevna from Orchanie, and on the 24th of July Osman's strength was increased by 14 battalions and a battery from Sofia. In order to secure his line of communications, on the 25th of July he sent a force of 6 battalions and 1 battery under Rifaat Pasha to occupy Lovcha (Lovats), where they entrenched themselves.

The Plevna garrison now numbered 20,000 (35 battalions, 8 squadrons, 57 guns and 400 mounted irregulars), who were organized in two wings with a general reserve. Adil Pasha commanded the left wing consisting of 12 battalions, 3 batteries and 2 squadrons, and held the ground from the Vid bridge to Grivitza; Hassan Sabri Pasha commanded the right wing, of equal strength, covering from Grivitza to the south. The remainder, as general reserve, was posted on the crest and slopes of the hill east of the town, with one battalion in Plevna itself. The west front was not fortified till October. Trenches were
the neighbourhood of Krishin, temporarily occupied two redoubts, but a heavy counter-stroke by the Turkish reserves forced him back with severe loss. The Russians retreated, the northern column to Tristenik and Karagak, the southern to Ponrodim. Their losses amounted to 7,300, while the Turkish losses exceeded 2,000. Had the Turkish garrison of Lovcha been called in, the result would have been still more disastrous to the Russians.

The victory was decisive, but Osman again failed to pursue. His troops were elated by success, the moral of the enemy severely shaken, the undependable Russian bridge over the Danube was within 40 m. of him, but he lost his opportunity, and continued himself with strengthening his defensive works. It is said that he was tied down to Plevna by orders from Constantinople.

The Russians now concentrated all their available forces against Plevna and called in the aid of the Rumanians. By the end of August they had assembled a force of 74,000 infantry, 10,000 cavalry and 440 guns, including 24 siege guns, about 100,000 men in all. On the 30th of August Osman moved out of Plevna with all his cavalry, 3 batteries of artillery and 19 battalions of infantry, and on the 31st attacked the Russians about Pelishat. He returned to Plevna the same evening. The Turks lost 1,300 and the Russians 1,000 men. The Russians determined to occupy Lovcha, and so cut Osman's communications before again attacking Plevna. After three days' fighting this was accomplished by Skobelev, acting under Imereitinski, with a force of 20,000 men, on the 3rd of September. Osman moved out to the relief of the garrison that day with a strong column, but, finding he was too late, returned to Plevna on the 6th. The survivors from Lovcha were re-formed into 3 battalions, including which Osman had been reinforced by 13 battalions, 23 batteries of artillery and 11 squadrons of cavalry. His strength was now 30,000, with 72 guns, 46 battalions, 19 squadrons and 12 batteries. This force was organized in 4 approximately equal commands, the northern, southern, eastern and southern, and a general reserve.

The Russians moved to their preliminary positions on the night of September 6th-7th. Their plan was for the Rumanians, the IX. and IV. corps and Imereitinski's column to attack the north-east, south-east and south fronts simultaneously. An artillery bombardment began at 6 a.m. on the 7th of September, was carried on till 3 p.m. on the 11th, when the infantry advanced. The Rumanians took one Grivitzat redoubt; Skobelev occupied two redoubts on the south front, but the centre attack on the Radischevo front failed. On the 12th the Turks recaptured the southern redoubts, the Rumanians remained in possession of the Grivitzat redoubt, but the Russian losses already amounted to 18,000 and they withdrew, and entrenched themselves on a line Verbitza-Radischevo, with cavalry on either flank to the Vid. The Turkish losses totalled 5,000, of which only a few hundred were caused by the artillery fire of the first few days. There was no question of pursuit. The Russians were greatly superior in numbers and the Turks were completely exhausted.

Several causes contributed to the Russian defeat. The Russian bombardment, at ranges beyond the powers of their guns and lacking the co-operation of the infantry to give them a target, had been useless. No reconnaissance had been made of the position. The infantry attacks were not simultaneous, and were beaten in detail, besides which, they were spread over the whole of a strongly fortified front in equal strength, instead of being pressed home at definite points. The lack of unity of command, in that the commander-in-chief interfered with the dispositions and conduct of the operations as arranged by the commander of the Plevna forces also militated against the Russian success.

This was the last open-force attack on Osman's lines. General Todleben, the defender of Sevastopol, was now entrusted with the conduct of the siege, and he determined to complete the investment, which was accomplished by the 24th of October, Osman's request to retire from Plevna having been refused by Constantinople. Supplies eventually gave out and a sortie on the night of the 9th–10th of December failed, with the result that he and his army capitulated.

Plevna is a striking example of the futility of the purely passive defence, which is doomed to failure however tenaciously carried out. Osman Pasha repelled three Russian attacks and practically held the whole Russian army. It remained for the other Turkish forces in the field to take the offensive and by a vigorous counterstroke to reap the fruits of his successes. Victories which are not followed up are useless. War without strategy is mere butchery. The position of Plevna, threatening a passage of the Danube, was of the utmost importance, but there was no necessity for the Russians to attack the position. On the eastern flank was an army stronger than Osman's and the fortress of Rustchuk was nearer the bridge than Plevna, but they did not consider it necessary to attack them. They might have contained Osman's force as they did the army under Mehemet Ali, and either awaited his attack or attacked when he evacuated the position. They failed to realize the resisting force of improvised fortifications and the strength conferred by extensive and well-registered entrenchments, and despising their adversary made direct frontal attacks on a well- fortified position, instead of aiming at a flank or the rear. The part played by Plevna in the war was due in the first place to the imaginary importance set by the Russians on its capture, and later to their faulty procedure in attack on the one hand, and to the skill evinced by the Turks in fortifying and defending the position on the other. (J. H. V. C.)

PLEYEL, IGNAZ JOSEPH (1757–1831), Austrian musician, was born at Ruppersthal, near Vienna, on the 1st of June 1757, the twenty-fourth son of a poor village schoolmaster. He studied the pianoforte under Van Hal (known in England as Vanhall), and in 1772 learned composition from Haydn, who became his dearest friend. He was appointed temporary maître de chapelle at Strasbourg in 1783, receiving a permanent appointment to the office in 1789. In 1791 he paid a successful visit to London. He narrowly escaped the guillotine on returning to Strasbourg, and was only saved by the existence of a warrant which he had written, and in which the inspiration could fairly be claimed to be on the side of liberty; so that he was permitted to remain until 1795, when he migrated to Paris. Here he opened a large music shop, published the first complete edition of Haydn's quartets, and founded, in 1807, the pianoforte manufacture which still bears his name. The latter years of his life were spent in agricultural pursuits. The July revolution of 1830 inflicted upon him a severe shock, and on the 14th of November 1831 he died in Paris.

Maria Pleyel, née Moke (1811–1875), the wife of his eldest son, Camille, was one of the most accomplished pianists of her time.

PLIGHT, an homonymous word now used chiefly with two meanings, (1) pledge, and (2) condition or state. The first appears more generally in the verbal form, "to plight one's troth," etc. and the second with a direct or implied sense of misfortune. The derivations of the two words show they are quite distinct in origin. The O. Eng. pliht meant danger or risk, hence risk of obligation (cf. Ger. Pflicht, Du. plicht, care, duty). The root pled or pleeg is probably also to be seen in the much disputed word "pledge." The M. Eng. pled or pley, on the other hand, is an adaptation of O. Fr. ploti, fold, and therefore a doublet of "pleat," but appears in the 14th century with the neutral sense of condition or state in general.
PLIMPL, A.—PLINY, THE ELDER

PLIMPL, ANDREW (c. 1763–1837), English miniature painter, was the son of a clock-maker at Wellington. Disliking his father’s business, he and his brother Nathaniel joined a party of gypsies and wandered about with them, eventually reaching London, where he presented himself to Mrs Cosway in 1781 and was engaged by her as studio boy. His skill in painting was quickly detected by Cosway, who sent him to a friend to learn drawing, and then received him into his own studio, where he remained until 1785, when he set up for himself in Great Maddox Street. It was of this artist that Cosway said “Andrew will be my Elisha,” adding with characteristic vanity, “if I am not constrained to carry my mantle up to Paradise with me.” Plimer married Joanna Louisa Knight, whose sister, Mary Ann, was his pupil and a well-known artist. He had five children, only one of whom, Louisa, married. He exhibited many times in the Royal Academy, resided for a while in Exeter, travelled a good deal through England, and died at Brighton and was buried at Hove. His miniatures are of great brilliance and in considerable demand among collectors. They are to be distinguished by the peculiar iridescent treatment of the hair and by the large full expressive eyes Plimer invariably gave to his female sitters, eyes resembling those of his own wife and daughters.

See Andrew and Nathaniel Plimer, by G. C. Williamson (London, 1903). (G. C. W.)

PLIMPL, NATHANIEL (1757–c. 1822), English miniature painter, was the brother of Andrew Plimer (q.v.). He worked for a while with Henry Bone the enameller, eventually entering Cosway’s studio. He exhibited at the Royal Academy from 1787 until 1815, when he is lost sight of, although he is said to have lived until 1822. He had four daughters, one of whom married the painter, Andrew Geddes, and left children. He exhibited twenty-six works, and many of his smaller portraits are of extreme beauty.

See Andrew and Nathaniel Plimer, by G. C. Williamson (London, 1903). (G. C. W.)

PLIMPL, SAMUEL (1824–1868), British politicians and social reformer, was born at Bristol on 10th of February 1824. Leaving school at an early age, he became a clerk, and rose to be manager of a brewery in Yorkshire. In 1853 he endeavoured to set up a business of his own in London as a coal merchant. The venture proved a failure, and Plimsoll was reduced to destitution. He has himself related how for a time he lived in a common lodging-house on 7s. 6d. a week. Through this experience he learnt to sympathise with the struggles of the poor; and when the success of his enterprise placed him in possession of a competence, he resolved to devote his leisure to the amelioration of their lot. His efforts were directed more especially against what were known as “cofnin-ships”—unseaworthy and overloaded vessels, often heavily insured, in which unscrupulous owners were allowed by the law to risk the lives of their crews. Plimsoll entered parliament as Liberal member for Derby in 1858, and endeavoured in vain to pass a bill dealing with the subject. In 1872 he published a work entitled Our Seamen, which made a great impression throughout the country. Accordingly, on Plimsoll’s motion in 1873, a royal commission was appointed, and in 1875 a government bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. On the 22nd of July, the premier, Disraeli, announced that the bill would be dropped. Plimsoll lost his self-control, applied the term “villains” to members of the house, and shook his fist in the Speaker’s face. Disraeli moved that he be reprimanded, but on the suggestion of Lord Harington agreed to adjourn the matter for a week to allow Plimsoll time for reflection. Eventually Plimsoll made an apology. The country, however, shared his view that the bill had been stifled by the pressure of the shipowners, and the popular agitation forced the government to pass a bill, which in the following year was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the Board of Trade. The mark that indicates the limit to which a ship may be loaded is generally known as Plimsoll’s mark. Plimsoll was re-elected for Derby at the general election of 1880 by a great majority, but gave up his seat to Sir W. Harcourt, in the belief that the latter, as home secretary, could advance the sailors’ interests more effectively than any private member. Though offered a seat by some thirty constituencies, he did not re-enter the house, and subsequently became estranged from the Liberal leaders by what he regarded as their breach of faith in neglecting the question of shipping reform. He held for some years the presidency of the Sailors’ and Firemen’s Union, raised a further agitation, marred by obvious exasperation, about the horrors of the cattle-ships. Later he visited the United States with the object, in which he did good service, of securing the adoption of a less bitter tone towards England in the historical textbooks used in American schools. He died at Folkestone on the 3rd of June 1895.

PLINLIMMON (Plynlimmon, Pamplumon, Pumplumon, Penlumon): Pumplumon is the name used locally: *pamp* means five: *lem*on, chimney, flag or beacon; *pen* head), a mountain of Wales of the height of 2493 ft., equidistant (about 10 m.) from Machynlleth and Llandiloos. Much inferior in elevation to Snowden or Cader Idris, Plinlimmon is certainly the most dangerous of the Welsh hills because of its quaking bogs. The scenery is comparatively poor, consisting chiefly of sheep-downs (in Montgomeryshire) and barren turberies (in Cardiganshire). If the name means “five-beacons,” only three of these are high, with a *corneddd* (stone-pile, probably a military or other landmark, rather than the legendary barrow or tomb) on each of the three. Plinlimmon is notable as the source of five streams—three small: the Rheidol, the Llwyd and the Gwy, and two larger and famous: the Wye (Gwy) and the Severn (Hafren).

The morasses of Plinlimmon saw many a struggle, notably the war to the knife between Owen Cymefig (q. v.), prince of Powys, and Hywel ab Cadogan. Here also Owen Glendower unfurled the banner of Welsh independence; from here, in 1401, he harassed the country, sacking Montgomery, burning Welshpool, and destroying Cwm Hir (long “combe,” or valley), of which some columns are said to be now in Llandiloos old church. On the side of Plinlimmon, some 2 m. from the Steddfadurginn inn, is Blaen Gwy (the point of the Wye), the course of the streamlet being traceable up to Pont-ryd-galed (the hard ford bridge), some 4 m. distant from the inn. Near this bridge are numerous barrows and cairns, on the right from Aberystwyth. There are slate quarries, with lead and copper mines. Machynlleth (perhaps *Meglana* in Roman times) has Owen Glendower’s “sene house” (1402), and is known as the scene of Glendower’s attempted assassination by Dafydd Gym. Llyn pen rhaiadr (the waterfall-head pool), or Pistyll y llyn (pool spout), is some 6 m. south of Machynlleth. Llandiloos has a trade in Plinlimmon slates and minerals besides flannel and wool manufactures.

PLINTH (Gr. πληθος, a square tile), the term in architecture given to the lower mouldings of a podium, pedestal or skirting; also to any rectangular block on which a statue or vase is placed, and in the Classic Orders to the square block of moderate height, under the base mouldings of the column or pedestal.

PLYN, THE ELDER. Gaius Plinius Secundus (c. A.D. 23–79), the author of the *Naturalis historia*, was the son of a Roman eques by the daughter of the senator Gaius Caecilius of Novum Comum. He was born at Comum, not (as is sometimes supposed) at Verona: it is only as a native of Gallia Transpadana that he calls Catullus of Verona his *conterruenatus*, or fellow-countryman, not his municeps, or fellow-townsmen (*Praef.* § 1). Before A.D. 35 (V. H. xxvii. 81) his father took him to Rome, where he was educated under his father’s friend, the poet and military commander, P. Pomponius Secundus, who inspired him with a passion of love for learning. Two or three years after the death of his father, Gnaeus Pliny saw some of their autograph writings in his preceptor’s library (xiii. 83), and he afterwards wrote that preceptor’s *Life*. He makes mention of the grammarians and rhetoricians, Remmius Palaemon and Arelius Fuscus (xiv. 49, xxiii. 152), and he may have been instructed by them. In Rome he studied botany in the garden of the aged Antonius Castor (xxv. 9), and saw the fine old lotus-trees in the grounds that had once belonged to Crassus (xvii. 5). He also viewed the
vast structure raised by Caligula (xxvii. 111), and probably witnessed the triumph of Claudius over Britain (iii. 110; A.D. 44). Under the influence of Seneca he became a keen student of philosophy and rhetoric, and began practising as an advocate.

He saw military service under Corbulo in Lower Germany (A.D. 47), taking part in the expedition against the Suebi, and the construction of the Chatti canal between the Maas and the Rhine (xxx. 2 and 5). As a young commander of cavalry (praefectus alae) he wrote in his winter-quarters a work on the use of missiles on horseback (de faculata equestri), with some account of the points of a good horse (vii. 162). In Gaul and Spain he learnt the meanings of a number of Celtic words (xxx. 40). He took note of sites associated with the Roman invasion of Germany, and, amid the scenes of the victories of Drusus, he had a dream in which the victor enjoined him to transmit his exploits to posterity (Plin. Epp. iii. 5, 4). The dream prompted Pliny to begin forthwith a history of all the wars between the Romans and the Germans. He probably accompanied his father's, Pomponius, on an expedition against the Chatti (A.D. 50), and visited Germany for a third time (57) as a comrade of the future emperor, Titus (Plae. 5 § 3). Under Nero he lived mainly in Rome. He mentions the map of Armenia and the neighbourhood of the Caspian Sea, which was sent to Rome by the staff of Corbulo in A.D. 58 (vi. 40). He also saw the building of Nero's "golden house" after the fire of 64 (xxxvi. 111). Meanwhile he was completing the twenty books of his History of the German Wars, the only authority expressly quoted in the first six books of the Annales of Tacitus (i. 66), and probably one of the principal authorities for the Germania. It was superseded by the writings of Tacitus, and, early in the first century, his account of the machus had little hope of finding a copy (Epp. xiv. 8). He also devoted much of his time to writing on the comparatively safe subjects of grammar and rhetoric. A detailed work on rhetoric, entitled Studiorum, was followed by eight books, Dubii sermonis (A.D. 67). Under his friend Vespasian he returned to the service of the state, serving as procurator in Gallia Narbonensis (70) and Hispania Tarraconensis (73), and also visiting the Provincia Belgica (74). During his stay in Spain he became familiar with the agriculture and the mines of the country, besides paying a visit to Africa (vii. 37). On his return to Italy he accepted office under Vespasian, whom he used to visit before daybreak for instructions before proceeding to his own duties, after which he devoted all the rest of his time to this study (Plin. Epp. iii. 5, 9). He completed a History of his Times in thirty-one books, possibly extending from the reign of Nero to that of Vespasian, and deliberately reserved it for publication after his decease (N. H., Prof. 20). It is quoted by Tacitus (Ann. xiii. 20, xv. 53; Hist. iii. 29), and is one of the authorities followed by Suetonius and Plutarch. He also virtually completed his great work, the Naturalis historia. The work had been planned under the rule of Nero. The materials collected for this purpose filled rather less than 160 volumes in A.D. 25, when Larcus Licinius, the praetorian legate of Hispania Tarraconensis, vainly offered to purchase them for a sum equivalent to more than £4,500. He dedicated the work to Titus in A.D. 77. Soon after this he was received from Vespasian the appointment of praefect of the Roman fleet at Misenum. On the 24th of August A.D. 70 he was stationed at Misenum, at the time of the great eruption of Vesuvius, which overwhelmed Pompeii and Herculanum. A desire to observe the phenomenon from a nearer point of view, and also to rescue some of his friends, from their perilous position on the shore of the Bay of Naples, led to his launching his galleys and crossing the bay to Stabiae (Castellamare), where he perished, in the fifty-sixth year of his age. The story of his last hours is told in an interesting letter addressed to his father twenty-seven years afterwards to Tacitus by the younger Pliny, nephew and heir, the Younger Pliny (Epp. vii. 16), who also sends to another correspondent an account of his uncle's writings and his manner of life (iii. 5)—

"He began to work long before daybreak... He read nothing without making extracts; he used even to say that there was no book so bad as not to contain something of value. In the country it was only the time when he was actually in his bath that was ever free from study. When travelling, as though freed from every other care, he devoted himself to study alone... In short, he deemed all time wasted that was not employed in study."

The only fruit of all this unwearied industry that has survived to our own times is the Naturalis historia, a work which in its present form consists of thirty-seven books, the first book including a characteristic preface and tables of contents, as well as lists of authorities, which were originally prefixed to each of the following books. These lists of authorities, which are as follows: i., mathematical and physical description of the world; iii.-vi., geography and ethnography; vii., anthropology and human physiology; viii.-xii., zoology; xii.-xxvii., botany, including agriculture, horticulture and materia medica; xxviii.-xxx., medical zoology; xxxii.-xxxiv., mineralogy, especially in its application to life and art, including chasing in silver (xxxii. 154-275), statuary in bronze (xxxv. 5-149), modelling (132-158), and sculpture in marble (xxxvi.).

He apparently published the first ten books himself in A.D. 77, and was engaged on revising and enlarging the rest during the two remaining years of his life. The arrangements were probably made with little, if any, revision by the author's nephew, who, when telling the story of a tame dolphin, and describing the floating islands of the Vadimonian Lake, thirty years later (vii. 20, ix. 33), has apparently forgotten that both are to be found in his uncle's work (ii. 209, ix. 26). He describes the Naturalis historia, as a Natura historia, and characterizes it as a "work that is learned and full of matter, and as varied as nature herself." The absence of the author's final revision may partly account for many repetitions, and for some contradictions, for mistakes in passages borrowed from Greek authors, and for the insertion of marginal additions at wrong places in the text.

In the preface the author claims to have stated 20,000 facts gathered from some 2000 books and from 100 select authors. The extant lists of his authorities amount to many more than 400, including 146 of Roman and 327 of Greek and other sources of the ancient world. The list is not exhaustive, and is probably not the subject matter of each book. This has been clearly shown in Heinrich Brunn's Disputatio (Bonn, 1856).

Pliny's principal authority was Varro. In the geographical books Varro is supplemented by the topographical comments of Agrrippa, which were compiled by the emperor Augustus; for his zoology he relies largely on Aristotle and on Juva, the scholarly Mauretanian king; students could obtain a copy of his works from a certain Ula in Africa as a sort of principal guide in botany. Theophrastus is also named in his Indices. In the History of Art the original Greek authorities are Duris of Samos (born c. 340 B.C.), Xeno- dus of Lampsis (fl. 265-255 B.C.), and Alcibiades (fl. 305-265 B.C.). The anecdotes have been ascribed to Duris (xxxiv. 61. Lysippan Scydonium Duris negavit ultius non sit discipulum, &c.); the notices of the successive developments of art, and the list of workers in bronze and painters, to Xenoocrates; and a large part of miscellaneous information to Antigonus. The last two authorities are named in connexion with Parrhasius (xxxv. 68, harci glioriam concersere Antigonum et Xenocrates, qui de pictura serpente), while Antigonus is named in the Indices of xxxii.-xxxvi., as a writer on the "tireous" art. Greek epigrams contribute their share in Pliny's descriptions of pictures and statues. One of the minor authorities for books xxxiv.-xxxvii. is Helioborus (fl. 150 B.C.), the author of a work on painting. An important place is assigned to Pasites of Naples (fl. 88 B.C.), the author of a work in five volumes on famous works of art (xxxvi. 46), probably incorrect dating rule, follow the order of the subject matter of each book. This has been clearly shown in Heinrich Brunn's Disputatio (Bonh, 1856).

Pliny's knowledge of architecture is based on several classical authorities, of which he often quotes (e.g. xxxiv. 56, xxxv. 113, 156, xxxvi. 17, 37, 41). Varro probably dealt with the history of art in connexion with architecture, which was included in his Discipinae. For a number of subjects, including a work on the making of metal vessels, the author's works are followed by the discipinae of the adjacent islands, Pliny was indebted to the general, statesman, orator and historian, Gaius Licinius Mucianus, who died before A.D. 77. Pliny mentions the works of art collected by Vespasian in the Temple of Haedus, and his other another, of which much of his information as to the position of such works in Rome is due to books, and not to personal observation. The main merit of his account of ancient art, the only classical work of its kind, is that it is a compilation ultimately founded on the lost text-books of Xenoocrates and on the biographies of Duris and Antigonus.
He shows no special aptitude for art criticism; in several passages, however, he gives proof of independent observation (xxxix. 38, 46, 63, xxxv. 17, 20, 116 seq.). He prefers the marble Laocoon in the palace of Titus to all the pictures and bronzes in the world (xxxvi. 37); in the temple near the Flaminian Circus he adores the Ares and the Aphrodite of Scopas, "which would suffice to give renown to any other spot." "At Rome indeed (he adds) the works of art are legion; besides, one effaces another from the memory and, however beautiful their form and general design, God has displayed himself to men in the overpowering claims of duty and business; for to adore art we need leisure and profound stillness" (ibid. 26-27).

Like many of the finest spirits under the early empire, Pliny was an adherent to the Stoics. He was acquainted with their noblest representative, Thrasea Pactus, and he also came under the influence of Seneca. The Stoics gave to the study of nature, while their moral teaching was agreeable to one who, in his literary work, was unselfishly eager to benefit and to instruct his contemporaries (Prof. 16, xxxviii. 2, xlix. 3). He was also influenced by the Epicurean and the Academic and the revived Pythagorean schools. But his view of nature and of God is essentially Stoic. It was only (he declares) the weakness of humanity that had embodied the Being of God in many human forms endowed with human faults and vices (ii. 148). The Godhead was really one; it was the soul of the eternal world, displaying its beneficence on the earth, as well as in the sun and stars (ii. 147 seq., 154 seq.). The existence of a divine Providence was uncertain (i. 19), but the belief in its existence and in the punishment of wrong-doing was salutary (ii. 20); and the reward of virtue consisted in the man's own happiness of mind and body. It resembled God in doing good to man (i. 18, Deus est mortali juvere mortalem, et haec ad aeternum gloriam vis). It was wrong to inquire into the future and to do violence to nature by resorting to magical arts (ii. 114, xxx. 3); but the significance of prodigies and portents is not denied (ii. 92, 100, 232). Pliny's view of life is gloomy; he regards the human race as plunged in ruin and in misery (ii. 24, viii. 139). Against luxury and moral corruption he indulges in declamations, which are so frequent that (like those of Seneca) they at last pall upon the reader; and his rhetorical flourishes against practically useless inventions (such as the notion of navigation) are wanting in good sense and good taste (xix. 6).

With the proud national spirit of a Roman he combines an admiration of the virtues by which the republic had attained its greatness (xvi. 14, xxxvii. 3, xxxvii. 201). He does not suppress historical facts unfavourable to Rome (xxxiv. 139), and while he honours eminent members of distinguished Roman houses, he is free from Livy's undue partiality for the aristocracy. The agricultural classes and the old landlords of the equestrian order (Cincinnatus, Curius Dentatus, Serranus and the Elder Cato) are to him the pillars of the state; and he bitterly laments the decline of agriculture in Italy (xviii. 31 and 35, latifundia perdiderce Italian). Accordingly, for the early history of Rome, he prefers following the praet-Augustin writers; but he regards the imperial power as indispensable for the government of the empire, and he hails the salutaris exorsus Vespasiani (xxxii. 51). At the conclusion of his literary labours, as the only Roman who had ever taken for his theme the whole realm of nature, he prays for the blessing of the universal mother on his completed work.

In literature he assigns the highest place to Homer and to Cicero (xvii. 37 seq.); and the next to Virgil. He takes a keen interest in nature, and in the natural sciences, studying them in a way that was then new in Rome, while the small esteem in which studies of this kind were held does not deter him from embarking on them (xxi. 15). The scheme of his great work is vast and comprehensive, being nothing short of an encyclopaedia of learning and of art so far as they are connected with nature or draw their materials from it. With a view to this work he studied the official authorities on each subject and was most assiduous in making excerpts from their pages. His indices auctorum are, in some cases, the authorities which he has actually consulted (though in this respect they are not exhaustive); in other cases, they represent the principal writers on the subject, whose names are borrowed second-hand for his immediate authorities. He frankly acknowledges his obligations to all his predecessors in a phrase that deserves to be proverbial (Prof. 21, plenum ingenii pudoris fideris pro quos praebes). He had neither the temperament for original investigation, nor the patience to go deeply into any subject; it is obvious that one who spent all his time in reading and in writing, and in making excerpts from his predecessors, had none left for mature and independent thought, or for patient experimental observation of the phenomena of nature. But it must not be forgotten that it was his scientific curiosity as to the phenomena of the eruption of Vesuvius that brought his life of unwearied study to a premature end; and any criticism of his faults of omission is disarmed by the candour of the confession in his preface: nec dubitamus nulla esse quae et nos praeceperint; homines enim sumus et occupati officiis.

His style betrays the unhealthy influence of Seneca. It aims less at clearness and vividness than at epigrammatic point. It abounds not only in antitheses, but also in questions and exclamations, tropes and metaphors, and other mannerisms of the silver age. The rhetorical and artistic form of the sentence is sacrificed to a passion for emphasis that delights in deferring the point to the close of the period. The structure of the sentence is also apt to be loose and straggling. There is an excessive use of the ablative absolute, and ablative phrases are often appended in a kind of vague "apposition" to express the author's own opinion of an immediately previous statement, e.g. xxxv. 80, (Apelles) obtinet se praeclarus, quod nonum de tabula scit tollere, memorabilis procepio nocte subepe nimium diligentiam.

About the middle of the 3rd century an abstract of the general portion of Pliny's work was produced by Solinus; and, early in the 4th, the medical passages were collected in the Medicina Plinii. Early in the 8th we find Bede in possession of an excellent MS. of the whole work. In the 9th Alcuin sends to Charlemagne a collection of Great Learning from Serranus and Decius; and in the 12th and 13th centuries Pliny's works were divided into two parts, and MSS. of them in Latin, and in Greek, were current in Germany and, especially, in Italy. A MS. at the Bibliotheque de l'Ecole of Paris contains only books xxxii.-xxxvii. Robert of Cricklade, prior of St Frideswide at Oxford, dedicated to Henry II. a De Florario consisting of nine books of selections taken from one of the MSS. of this class, which has been recently recognized as sometimes supplying us with the only evidence for the true text. Among the later MSS. the codex Vesalianus, formerly at Besancon (11th century), contains books xxxii.-xxxvii., divided into 15 folio quires, by vellum and Leiden respectively, while there is also a transcript of the same MSS. at Leiden.

In modern times the work has been the theme of a generous applause. In several of his volumes (ed. Jaffe; ed. Detlefsen; ed. E. T., 1848), Jacob Grimm, in the first paragraph of c. 37 of his Deutsche Mythologie, writing with his own fellow-countrymen in view, has commended Pliny for condescending, in the midst of his researches into the science of ancient Greece and the world of plants and animals, and has even praised him for the pains that he bestowed on his style. It may be added that a special interest attaches to his account of the manufacture of the papyrius (xii. 60-83), and of the different kinds of purple dye (ix. 130), while his description of the notes of the nightingale is an elaborate example of his occasional felicity of phrase (xxix. 81 seq.). Most of the recent research on Pliny has been concentrated on the investigation of his authorities, especially those which he followed in his chapters on the history of art—the only ancient account of that subject which has survived. The letters C. Plinii, by which the letters C. Plinius have been reproduced by Cades (v. 211) from the original in the Vannutelli collection, it represents an ancient Roman with an almost completely bald forehead and a double chin; and is almost certainly a portrait, not of Pliny the younger but for the purpose of the statue of both the Plinies, clad in the garb of scholars of the year 1500, may be seen in the niches on either side of the main entrance to the cathedral church of Como. The elder Pliny's anecdotes of Graecia supplied Vasari with the subjects of the frescoes which still adorn the interior of his former home at Arezzo.

BIBLIOGRAPHY.—Editions by Hermolaus Bar bara (Rome, 1607-1608); Georges Rigaud (Lyon, 1609); Grotius (Leiden, 1660); Hardouin (Paris, 1685); Haberlandt (Berlin, 1788); an English literal index by O. Schneider (Gottinga, 1833-1835); L. van Jan (Leipzig, 1854-1865); D. Detlefsen (Berlin, 1866-1873); and critical edition (18th century) by Detlefsen; (19th century) by (Eng. trans., Philomene Holland (London, 1861); French, Litter (1852); Chrestomathia Pliniana, L. Urlich, with excellent Einleitung (Berlin, 1857); The Elder Pliny's Chapters on the History
of Art, trans. by J. K. B. Leckie, with commentary, and historical introduction by E. Sellen. London, 1893. On Pliny’s voluminous output, see Rom. Itinern. i. 288; on the Dioriforos Plinia of Robert of Cricklade, K. Rück, in S. Ber. of Munich Acad., May 3, 1902, pp. 195–205 (1903). On Pliny’s Authorities, see Carl F. Becker, Die griechischen und römischen Quellen, ii. 2, and Dideleuten, Quellen und Forschungen zur alten Gesch. und Geog. (1904 and 1908); on his Religion, Vorhauer (Innsbruck, 1860); his Cosmology, Fries (Breslau, 1862); his Botany, Brosig (Gaudenz, 1883); Sprengel (Marburg, 1890), and in Rhein. Mus. (1877) vol. ix.; Blümner, in Rhein. Mus. (1877); L. Urlich (Würzburg, 1876); Oeser (Leipzig, 1885); Dusig (Metz, 1885); H. Voigt (Halle, 1887); H. L. Urlich’s (Würzburg, 1887); Holzwerda, in Mnemos. (1889); F. Münzer, in Hermes (1895, and Berlin, 1897); Kalkmann (Berlin, 1898).

The fragments of the eight books, Dubi sermonis, have been collected by J. W. Beck (Leipzig, 1894). For further bibliographical details, see Mayor, Lat. Lit. (1875), 136–138; and Schanz, Korn. Lit. (Munich, 1903), §§ 499–504.

PLINY, THE YOUNGER. Publius Caecilius Secundus, later known as Gaius Plinius Caecilius Secundus (A.D. c. 61–c. 113), Latin author of the Letters and the Panegyric on Trajan, was the second son of Lucius Caecilius Cilo, by Plinia, the sister of the Elder Pliny. He was born at Novum Comum, the modern Como, the date of his birth being approximately determined by the fact that he was in his 18th year at the death of his uncle in August A.D. 79 (Ep. vi. 20, 5). Having lost his father at an early age, he owed much to his mother and to his guardian, Verginius Rufus, who had twice filled the office of consul and had twice refused the purple (i. 1, 8). He owed still more to his uncle. When the Elder Pliny was summoned to Rome by Vespasian in A.D. 72, he was probably accompanied by his nephew, who there went through the usual course of education in Roman literature and in Greek, and at the age of fourteen composed a “Greek tragedy” (vii. 4, 2). He afterwards studied philosophy and rhetoric under Nicetis Sacerdos and Quintilian (vi. 6, 3, ii. 14, 9), and modelled his own oratorical style on that of Demosthenes, Cicero and Calvus (i. 2). The Elder Pliny inspired his nephew with something of his own indomitable industry; and in August 79, when the author of the Historia naturalis lost his life in the famous eruption of the Etna, it was the Elder Pliny and the mother of the Younger Pliny who first described the signs of the approaching visitation, and, some twenty-seven years later, it was the Younger Pliny who wrote a graphic account of the last hours of his uncle, in a letter addressed to the historian Tacitus (vi. 16). By his will the Elder Pliny had made his nephew his adopted son, and the latter now assumed the nomen and praenomen of his adoptive father.

A year later he made his first public appearance as an advocate (v. 8, 8), and soon afterwards became a member of the board of decemviri stiliibus judicandis, which was associated with the praetor in the presidency of the centumviral court. Early in the reign of Domitian he served as a military tribune in Syria (A.D. 87 or 88), devoting part of his leisure to the study of philosophy under the Stoic Euphrates (i. 16, 2). On returning to Rome he was nominated to the honorary office of sevir equitum romanorum, and was actively engaged as a pleader before the centumviri, the chancery court of Rome (vi. 12, 2).

His official career began in A.D. 89, when he was nominated by Domitian as one of the twenty quaestors. He thus became a member of the senate for the rest of his life. In December 91 he was made tribune, and, during his tenure of that office, withdrew from practice at the bar (i. 23). Early in 93 he was elected praetor (iii. 11, 2), and, in his year of office, was also the counsel for the impeachment of Baetica Musa (i. 7), the procurator of Hispania Baetica (iii. 4, vi. 29, vii. 33). During the latest and darkest years of Domitian he deemed it prudent to withdraw from public affairs, but his financial abilities were recognized by his nomination in 94 or 95 to the profectura aerarii militaris (ix. 13, 11).

On the death of Domitian and the accession of Nerva he delivered a speech (subsequently published) in prosecution of Publicius Cetius, who had been foremost in the attack on Helividius Priscus (ix. 13). Early in 98 he was promoted to the position of praefect of the public treasury in the temple of Saturn. After the accession of Trajan in the same year, Pliny remained associated with Tacitus in the impeachment of Marius Priscus for his maladministration of the province of Africa (ii. 11). The trial was held under the presidency of the emperor, who had already nominated him consul sufectus for part of the year A.D. 100. The formal oration of thanks for this nomination, described by Pliny himself as his grotiarius actio (iii. 13 and 18, 1), is called in the MSS. the Panegyricus Traiano dicus.

The following year was marked by the death of Silius Italicus and Martial, who are gracefully commemorated in two of his Letters (iii. 7 and 21). It is probable that in 103–104 he was promoted to a place in the college of Augurs, vacated by his friend Frontinus (iv. 8), and that in 105 he was appointed curator of the river Tiber (v. 14, 2). In the same year he employed part of his leisure in producing a volume of hendecasyllabic verse (iv. 14, v. 16). He usually spent the winter at his seaside villa on the Latian coast near Laurentum, and the summer at one of his country houses, either among the Tuscan hills, near Tifernum, or on the lake of Como, or at Tusculum, Tibur or Praeneste.

It was probably in 104, and again in 106, that he was retained for the defence of a governor of Bithynia, thus becoming familiar with the affairs of a province which needed a thorough reorganization. Accordingly, about 111, he was selected by Trajan as governor of Bithynia, under the special title of “legate praeprorector with consular power.” He reached Bithynia in September, held office for fifteen months or more, and probably died in 113.

His health was far from robust. He speaks of his delicate frame (gracilitatis mem) and was apt to suffer from weakness of the eyes (vii. 21) and of the throat or chest (ii. 11, 13). Frugal and abstemious in his diet (i. 15; iii. 1 and 12), studious and methodical in his habits (i. 6, v. 18, ix. 36 and 40), he took a quiet delight in some of the gentler forms of outdoor recreation. We are startled to find him telling Tacitus of his interest in hunting the wild boar, but he is careful to add that, while the beaters were at work, he sat beside the nets and was busily taking notes, thus combining the cult of Minerva with that of Diana (i. 6). He also tells the historian that, when his uncle left Misenum to take a nearer view of the eruption of Vesuvius, he preferred to stay behind, making an abstract of a book of Livy (vi. 20, 5).

Among his friends were Tacitus and Suetonius, as well as Frontinus, Martial and Silius Italicus; and the Stoics, Musonius and Helvidius Priscus. He was thrice married; on the death of his second wife without issue, Trajan conferred on him the jus trium librorum (A.D. 98), and, before 105, he found a third wife in the accomplished and amiable Calpurnia (iv. 15). He was generous in his private and his public benefactions (i. 10, 2, ii. 4, 2, vi. 32). At his Tuscan villa near Tifernum Tiberinum (iv. 1, 4), the modern Città di Castello, he set up a temple at his own expense and adorned it with statues of Nerva and Trajan (x. 8). In his lifetime he founded and endowed a library at his native place (i. 8, v. 7), and, besides promoting local education (iv. 13), established an institute for the maintenance and instruction of the sons and daughters of free-born parents (vii. 18). By his will he left a large sum for the building and the perpetual repair of public baths, and the interest of a still larger sum for the benefit of one hundred freedmen of the testator and, ultimately, for an altar on that spot.

On a marble slab that once adorned the public baths at Comum, his distinctions were recorded in a long inscription, which was afterwards removed to Milan. It was there broken into six square pieces, four of which were built into a tomb within the great church of Sant’ Ambrogio. Of these four fragments only one survives, but with the aid of transcripts of the other three made by Crescynius of Ancona in 1442, the whole was
PLINY, THE YOUNGER

845

restored by Mommsen [C.I.L. v. 5262]. It is to the following effect:

Gaius Plinius Caecilius [Secundus], son of Lucius, of the Ufentine tribe; consul; augur; legate-proprietor of the province of Pontus and Bithynia; prefect of the Province of the White Mosaic (i.e., of the Atalante); praefect of the library, the praefect of the library, the praefect of the Treasury of the Temple of Minerva, curator of the plebs; emperor's quaestor, sevir of the Roman knights; military tribune of the ephibic Gallic legion; decemvir for the adjudication of suits; provided by will for the erection of baths at a cost of 300,000 sesterces (3,2400) and, furthermore, for maintenance, 200,000 sesterces (£1600); likewise, for the support of one hundred of his own books as well as those of himself and of his predecessors, the imperial and royal scribes. (C. 155,6000) the eventual accretions whereof he devised to the townsfolk for a public entertainment;...likewise, in his lifetime he gave for the support of sons and daughters of the townsfolk, for the maintenance of the library, and, for the maintenance of the library, 100,000 sesterces (£800).

With the exception of two mediocre sets of verses, quoted by himself (vii. 4 and 9), his poems have perished. His speeches were apt to be prolix, and he defended their prolixity on principle (i. 20). He was apparently the first to make a practice of reciting his speeches before a gathering of his friends before finally publishing them (iii. 18). The only speech that has survived is the Panegyric on Trajan, first delivered by Pliny in the emperor's presence, next recited to the orator's friends for the space of three days, and ultimately published in an expanded and revised form (Ep. ii. 9). It is with the fullest account of the emperor's antecedents, and of his policy during the first two years and a half of his rule.

It describes his entering Rome on foot, amid the rejoicings of the citizens; his liberality towards his soldiers and to the citizens of Rome, a liberality that was extended even to persons under eleven years of age; his charities for the maintenance of the children of the poor; his remission of succession-duities in cases where the property was small or the heirs members of the testator's family; his establishment of free trade in corn between the various parts of the empire; his attention to the maintenance of the public buildings, and general enactments for "high treason"; his punishment of informers; his abolition of pantomimes; his repairs of public buildings and his extension and embellishment of the Circus Maximus. The speech was discovered by Ausupea at Mainz in 1432, as part of a collection of Panegyrici; and it was first printed by Fr. Puteolanus at Milan about fifty years later.

Besides the Panegyric, we possess the nine books of Pliny's Letters, and a separate book containing his Correspondence with Tiberius.

In the first letter of the first book Pliny states that he has collected certain of his letters without regard to chronological order (non serva temporis ordine). Pliny's learned biographer, the Rev. Mr. Heber, has shown that the arrangement assumed by most editors of the letters is (to use the words of Professor R. M. Ollendorf, who has published a new octavo edition, 1892):--

I. 1.-ii. 100. II. (i. 101.-ii. 102.) III. 103.-vi. (i. 106.) VII. (i. 107.-vii. 108.) VIII. (i. 109.) IX. (i. 110.-i. 111.) X. (i. 112.) XI. (i. 113.) XII. (i. 114.) XIII. (i. 115.) XIV. (i. 116.) XV. (i. 117.) XVI. (i. 118.) XVII. (i. 119.) XVIII. (i. 120.)

In his Letters Pliny presents us with a picture of the varied interests of a cultivated Roman gentleman. The etiquette of the imperial circle, scenes from the law-courts and the recreation-room, the reunions of dilettanti and philosophers, the busy life of the capital or of the municipal town, the recreations of the seaside and of the country—all these he brings vividly before our eyes. He elaborately describes his Laurentine and his Tuscan villa, and frankly tells us how he spends the day at each (i. 17. v. 6. ix. 36. and 40; expatiates on his verses and his speeches, his holiday-tasks in Umbria (vii. 9. ix. 10), and his happy memories of the Lake of Como (i. 5. 6). He gives an extensive account of a statue of Corinthian bronze he has recently purchased (iii. 6). He is interested in providing a teacher of rhetoric for the place of his birth (iv. 13); he exults in the devotion of his wife, Calpurnia (vi. 19); towards his servants he is an indulgent master (viii. 16); he intercedes on behalf of the freedman of a friend (ix. 21), and, when a freedman of his own is in delicate health, sends him first to Egypt and afterwards to the Riviera (v. 19). He consults Suetonius on the interpretation of dreams (i. 18); he presents another of his correspondents with a batch of ghost-stories (vii. 27) or a marvellous tale about a tame dolphin on the north coast of Africa (ix. 33). He discourses on the beauties of the Ciltumnus (viii. 5) and the floating islands of the Sinonian lake (vii. 20). He describes an tour to Vesuvius in connexion with the last days of the Elder Pliny (vi. 16 and 20), giving elsewhere an account of his manner of life and a list of his writings (iii. 5). He laments the death of Silius Italicus (iii. 7), of Martial (iii. 21), and of Verginius Rufus (ii. 1), and of others less known to fame. He takes as his models Cicero and Tacitus (vii. 20), whose name is so often (to his delight) associated with his own (ix. 23). He rejoices to learn that his writings are read at Lyons (ix. 11). He complains of the inanity of circus-races (ix. 6), of the decay of interest in public recitations (i. 15), of his taste in matters of hospitality and of the expense of the suppers at his house; the social duties of Rome (i. 9). He lays down the principles that should guide a Roman governor in Greece (viii. 24); he maintains the cause of the oppressed provinces of Spain and Africa; and he exposes the iniquities of the informer Regulus, the only living man whom he attacks in his Letters, going so far as to denounce him as omnium bipedum nequissimus (i. 5. 14).

The Letters are models of graceful thought and refined expression, each of them dealing with a single topic and generally ending with an epigrammatic point. They were imitated by Symmachus (Macrobius v. 1. 7 and by Apollinaris Sidonius (Ep. ii. 11. 22). In them Pliny expresses the general condition and aspect of the letters of Verona (10th century), who quotes a passage from i. 5. 16 (Migne, cxxxi. p. 391). Selections were included in a volume of Flores compiled at Verona in 1329; and a MS. of bk. i.-vii. and ix. was discovered by Guarino at Venice in 1419. These books were printed in the editio princeps (Venice, 1471). Part of bk. viii. appeared for the first time at the end of the next edition (Rome, c. 1474). The whole of bk. viii. was first published in its proper place by Aldus Manutius (Venice, 1508).

Pliny's Correspondence with Trajan supplies us with many interesting details as to the government of Bithynia, and as to the relations between the emperor and the central authority. It is one of the greatest mercies of the strict and thorough Ruthenian conscientiousness of the emperor, and on the assiduity and the high principle which animated the emperor.

On reaching the province, Pliny celebrates the emperor's birthday, and proceeds to examine the finances of Prusa. His request for a surveyor to check the outlay on the public works is refused on the ground that the emperor has already given the works he is carrying on in Rome. He asks the emperor to sanction the repair of the ancient baths at Prusa, the building of an aqueduct at Nicomedia and a theatre at Nicaea, and the covering of a stream that has become a public nuisance at Amastris. When he consults the emperor as to the baths at Claudianopolis, the emperor severely replies: "You, who are on the spot, will be able to decide." Pliny answers: "I will refer the matter to Dio Chrysostom (the Bithynian friend of Nerva and Trajan), the emperor betrays not unnatural impatience in his response: potius non haerere, mi Scander carissime (82). Pliny asks for a fire-brigade, and the emperor not only grants his request but enforces its appointment (117). Owing to a destructive fire at Nicomedia, Pliny suggests the formation of a volunteer fire-brigade, limited to 150 members. The emperor is afraid that the fire-brigate might become a political faction, and therefore be strictly controlled (117). Pliny urges that the fire-brigade might become a political faction, and therefore be strictly controlled (117). Pliny urges that the fire-brigade might become a political faction, and therefore be strictly controlled (117).

Trajan's fear of factions and clubs in these two last cases has sometimes been connected with the question of his attitude towards the Christians, but the evidence is by no means conclusive. It is possible that he had never taken part in formal trials of Christians, and was therefore unfamiliar with precedents as to the extent of the investigation, and as to the degree of punishment that might be drawn between adults and those of tender years; and that
allowance might be made for any one who recanted. There was also the question whether any one should be punished simply for bearing the name of Christian or if he was found guilty of 'crimes associated with that name.' Hitherto, in the case of those who were hunted out and tormented, they had been let off before the three distinct times whether they were Christians, and, if they persisted in the admission, had ordered them to be taken to execution. Whatever might be the real character of their profession, he held that such persons of this kind ought not to beedicted, unless others no less "demented," who, being Roman citizens, would be sent to Rome for trial. Soon, as the natural consequence of these proceedings, the various cases had come before his notice. He had received an anonymous statement giving a list of accused persons. Some of them, who denied that they had ever been Christians, had consented to pray to the gods, to adore the image of the emperor, and blasphemized Christ. Others had admitted that they were Christians, but presently denied it, adding that they had ceased to be Christians for some years. All of these worshipped images of the gods and of the emperor, and blasphemed Christ. They averred that the sin and substance of their "fault" was that they had been accustomed to meet on a fixed day before daylight to sing in a hymn to Christ as God, and to bind themselves by a solemn oath (sacramento) to abstain from theft or robbery, or from adultery, perjury and dishonesty: after which they were wont to separate and to meet again for a common meal. This, however, they had ceased to do as soon as Pliny had published an edict in accordance with the emperor's edict. To ascertain the truth, he had also put to the torture two maid-servants described as deaconesses, but had discovered nothing beyond a puerile and extravagant superstition. He had accordingly put them to death, and the remaining cases were likewise disposed of. The question appeared to be worthy of such a consultation, especially in view of the number of persons of all ages and ranks, and of both sexes, who were impetrified. The contagion had spread through the whole city and provinces, and a rich harvest of the edible classes was still to be reaped. Temples that had been well pleased deserted were already beginning to be frequented, rites long intermitted were being renewed, and the trade in fodder for sacrificial victims was being re-established. It might be inferred from this how large a number might be reclaimed, if only room were granted for repentance.

Trajan in his reply (Epp. 97) expresses approval of Pliny's course of action in the case of the Christians brought before him. It was unjust, he says, to doubt or to punish those who had not been expelled. The persons in question were not to be hunted out, but if they were reported and were found guilty, they were to be punished. If, however, they had been Christians, and on the evidence of their denounced denial by worshipping the gods of Rome, he was to receive pardon. But no attention was to be paid to anonymous charges. It would be a bad precedent and unworthy of the spirit of the age. The view that the Christians were punished for being members of a collegium or sodalitas (once held by E. G. Hardy, and still maintained by Professor Merrill) is hard to reconcile with Pliny's own statement that the Christians had promptly obeyed the edict, and in accordance with the instructions issued to governors of provinces to search out and punish sacrilegious persons. (4) They had already been classed as outlaws, and the name of Christian in itself entailed condemnation. (5) This treatment was a settled principle of imperial policy, not established by the capricious action of any one emperor. (6) While Trajan felt bound to carry out the established principle his personal view was to some extent opposed to it. (7) A definite form of procedure had been established. (8) This procedure was followed by Pliny (W. M. Ramsay, The Church in the Roman Empire, p. 223).

It has been well observed by E. G. Hardy that the "double aspect of Trajan's rescript, which, while it theoretically condemned the Christians, practically gave them a certain security," explains "the different views which have since been taken of it; but by most of the church writers, and perhaps on the whole with justice, it has been regarded as favourable and as rather discouraging persecution than legalizing it" (Pliny's Correspondence, p. 270).

AUTHORITIES.—The correspondence with Trajan was apparently preserved in a single Paris MS.; Epp. 41-121 were first printed by Avantius of Verona (1602); and Epp. 1-40 by Aldus Manutius (1508). The original Ms. has vanished; but the "copy" supplied to the printers of the Aldine text was discovered by Mr. E. G. Hardy in the Bodleian in 1888. The two letters on the Christians were known to Tertullian (Apol. c. 2). The attacks on the genuineness of the whole or part of the collection have been refuted by Wrede (Leipzig, 1880).

For a critical edition of text, see H. Kell (Leipzig, 1870), with full index of names by Monms'en; for plain text, Kell (1853), &c., C. F. W. Müller (1903); the best annotated editions are those of Leander Schieler (1893) and G. E. Gering (1896-1896); of the Letters alone, G. Korte (1734), and the less trustworthy edition of M. Döring (1849); of bks. i. and ii., Cowan (1889); of iii., Mayor (1880), with life by G. H. Rendall; of iv., Duff (1900); of the Panegyricus, C. G. Schwarz (1846); of the Correspondence with Trajan, E. G. Hardy (1889); of Selected Letters, E. T. Merrill (1935); best Eng. trans. by J. D. Lewis (1897).

On Pliny's life, see the works by J. Masson (Amsterdam, 1796); H. Schöntag (Hof, 1876); and Giesen (Bonn, 1885). On the chronology of the letters, &c., Monms'en, in Hermes, iii. 31-114 (1886); trans. into French by Morel, 1873; criticized by Stobbe (Philologus, 1879); Gemoli (Halle, 1872); C. Peters (Philologus, 1873); Asbach (Rerum. Mus., 1881); and Schultz (Berlin, 1890). For the style, the works of H. Holstein (1862-1869); K. Kraut (1872); J. F. Lagrange (1872); and Morel (Grenoble, 1888). On the role of the Coloniae and the Campagna (1871), 411-415; Archiepisc., in the Builder (Feb. 8, 1890); Winnefeld, in Jabr. des. arch. Inst. (1891), pp. 201-217; and Magoun, in Trans. Amer. Philos. Assn. (1885).

(ed. 1889); Neumann, Der römische Staat und die allgemeine Kirche (1890) vol. i.; Monms'en, in Hist. Zeitschrift (1896); W. M. Ramsay, The Church in the Roman Empire (ed. 1893), ch. 10, pp. 196-225; and E. G. Hardy, Christianity and the Roman Government (1894), reprinted in Studies in Roman History (1906), pp. 1-162; with the literature quoted in these works and in Schan. Rom. Lit. § 643. (J. E. S. *).

PILOCENE (from the Gr. πλιός, μερες, και κόας, recent), in geology, the name given by Sir C. Lyell to the formations above the Miocene and below the Pliocene (Newer Pliocene) strata.

During this period the great land masses of the earth were rapidly approaching to the configuration which they exhibit at the present day. The marine Pliocene deposits are limited to comparatively few areas; in Europe, in the beginning of the period, the sea washed the shores of East Anglia and parts of the south coast of England; it extended well into Belgium and Holland and just touched here and there on the northern and north-western coasts of France; it sent an arm some distance up the valley of the

Guadalquivir and formed small bays on several points of the southern coast of France; and up the Rhone basin a considerable gulf reached as far as Lyons. Early in the period the sea covered much of Italy and Sicily; but the eastward extension of the ancient Mediterranean in south-east Europe, through the Danube basin, the Aral, north Caucasian and Caspian regions, continued to suffer the process of conversion to lagoons and large lakes which had begun in the Miocene.
PLIOCENE

Generally all over the world the majority of Pliocene formations are non-marine, and the limited and local nature of the elevations since the inception of the period has exposed to view only the shallow marginal marine deposits. The principal exception to the last statement is to be found in the Pliocene of Italy and Sicily, where a continuous crustal depression permitted the accumulation of great thicknesses of material, which later on, towards the close of the period, were elevated some thousands of feet. With these disconformities movements are associated the Italian volcanoes; Etna certainly began its career beneath the sea, for its older tufts are found interstratified with marine beds, and possibly some of the others had a similar origin. At the same time volcanic outbursts, some apparently comparable to that of Martinique in recent times, were taking place in central France, while far away in southern Sumatra thousands of feet of submarine tufts were being thrown out and deposited, and great lava flows were being erupted in Australia.

Considerable differences of opinion are exhibited among geologists as to the lower limits of the Pliocene formations; this is partly to be accounted for by the absence of widely-spread marine deposits, and partly by the comparatively short time-differences between the depositors. But, however, and hence the similarity of the faunas of contiguous strata-groups in local vertical series of beds. Following A. de Lapparent (Traité de géologie, 5th ed., 1906), we shall regard the Pliocene as divisible into three stages: an upper Sicilian stage, a middle Astian stage, and a lower Plaisian stage. Other writers, however, have selected a different nomenclature, which often involves a different grouping of the formations; thus E. Kayser in his Format ionskunde (3rd ed., 1908) distinguishes three stages under the names Arni an (upper), As tian (middle) and Messinian (lower) = Zanclean. The lower stage, however, includes the Pontian, Eppeheim, Pikermi and other formations which are here placed under the name of Lower Pliocene. This stage has been referred to a so-called Mio-Pliocene inter-period.

The Pliocene rocks of Britain now occupy but a small area in Norfolk, Suffolk and part of Essex; but from the presence of small outlying patches in Cornwall (St Erth and St Agnes), Dorsetshire (Dewlish) and Kent (Lenham), it is evident that the Pliocene Sea covered a considerable part of southern England. Moreover, these patches show by their present altitude above the sea that the Downs of Kent must have been elevated more than 830 ft., and the west coast of Cornwall 400 ft. since Pliocene times. The Pliocene rocks rest with strong unconformity upon the older strata in Britain. In the eastern counties the shelly beds, sandy beds are called "crag"; in the western the phos- phatic bones of whale, deer, mastodon, pig, tapir, rhinoceros, &c., and has been given the name of "crag". But in the Red Crag formations two distinct deposits underlie the red crag and sometimes the coralline crag. The last-named formation, known also as the "white" or "Suffolk crag," or as the "Bryozoan crag" (it was the presence of Bryozoa which led to the name "crag"), is essentially a shell bank, which was accumulated at a depth of from 20 to 40 fathoms. It is best exposed near Alderburgh and Gedgrave in Suffolk. The Red Crag is sandy, marine, shallow-water deposits, with an abundant fauna; they vary rapidly from point to point, and in general the more southern localities are richer in southern (older) forms than those farther north. The Norwich crag (fluvo-marine or mammaliferous crag) is not always very clearly marked off from the Red Crag. Marine fresh-water and land shells are found in these beds, together with many mammalian remains, including Elephas antiquus, Mastro- lithos, Euhyracodon, E. antiquus, Elephas antiquus, E. meridionalis, and other fish. The Forest-Bed group or Cromer forest-bed is exposed beneath the boulder clay cliffs of the Norfolk coast; it contains transported stumps of trees and many plants still familiar to us. Many large and many small marine molluscs and a large number of mammals, many of which are extinct (Marcellus, Carus, Iupus, Ursus spelaeus, Hyaena crocuta, Hippopotamus amphibius, Rinoceros erucaus, Elephas antiquus and E. meridionalis, E. antiquus, Orisus caecatus, O. inornatus, O. canus, Callabius and E. stenonis, Caster floer, Tapia europaea and many others). The only record of Pliocene remains in the northern part of England is from the coastal region of the Solway Firth, where remains found in a fissure in the limestone at Dove Holes, Derbyshire.

The Pliocene deposits of Belgium and Holland and the northern extremity of France are closely related with those of Britain, though in some places they are much thinner. The oldest marine beds may be traced from Lenham across the Channel at Calais and through Cassel to Diest. The newer marine Pliocene runs in a parallel belt to the north of the older beds through Antwerp. Belgian geologists have named the local Pliocene by the following groups (listed downwards): Poedelriani, Schasiclaisis, Casterliani, Diestian. F. W. Harmer (Quart. Journ. Geol. Soc., 1896 and 1900) proposed the following scheme for the Pliocene of Britain and the Low Countries:

Cromerian = Forest-bed of Cromer.
Cromerian (3rd)-Cromerian = Chillesford beds and Weybourne crag.
2. Lower crag.
3. Belgian = Red crag, comprising the Newbournian and Butleyan sub-stages.

Wiltonian = Walton crag and Podeerian and Schasiclaisis.
Gharian = Casterliani crag and Casterliani.
Diastian =mixian.

In addition to the deposits just mentioned in French Flanders, the early Pliocene sea has left numerous small patches of marls and sands in Belgium and France. In some instances the older marine gravels and marls of Pliasian and Astian ages occur in the depression of Roussillon, followed by Sicilian marls and gravel. In Languedoc (Montpellier, Nîmes, Béziers) marine marls and sands are the oldest deposits; the gravels generally form a very extensive layer of calcareous and arenaceous deposits, which is overlain by the ignitellaceous beds; gravel and loams constitute the uppermost beds. In the Rhone basin the earliest deposits are the Congeria beds of Bollene and their equivalents. In the English area, these beds are non-marine, and have the same name in Vienna, but resembles those of Italy and Russia. Then followed a marine invasion (groupe de Saint-Aries); these beds are now found at considerable elevations increasing northward up to 350 m. in the neighbourhood of Nice. In central France no marine beds are found, but many interesting and in some cases highly fossiliferous deposits occur in association with volcanic rocks, such as the lower conglomerate and upper phonolite breccia of Perrier (jusque), the Riesen brick (cinctres) and the basalt of the Cézallier, the diatomite of Ceyssac, &c. In Italy, Pliocene rocks form the low ranges of hills on both sides of the Apennines, hence the name of "sub-Apennine" given to these rocks by Fontana.

They are marine marls and sands; the blue marls which crop out near Rome at the base of Mt Mario and St Vatican with the succeeding sands and gravels; the conglomerate followed by deep-marls of Calabria, and the marls, sands, limestones and blue clay of Sicily, all belong to the Pliasian stage. To the next stage belong the yellow sands full of massive fossils, including the conglomerate of Castrovillari in Calabria and the white marls of the Val d’Arno. In the final (Sicilian) stage fluvio-lacustrine sands and gravels are found in Italy, except in Calabria and in Sicily where thick marine beds were formed. In Switzerland some of the deposits of Nagelfisch and Meieroth, and in the Alps, are of the same nature as the Calabrian and Sicilian deposits. In southeastern Europe a great series of sands and marls with lignites, termed the Paludina beds, rests directly upon the Pontian formation. From their great development in the Levant, they have been given the rank of a "Levantine stage" by von Hochstetter; they are found in Dalmatia, Croatia, Slovenia, Bosnia, Rumania, Bulgaria, southern Russia, the Cyclades, and the Caspian region. On the north coast of Africa marine and brackish sands and marls are found near the mouth of the Euphrates and on the Euphrates itself. On the coast of Florida and California, beds of great thicknesses, notably in the Merced series of San Francisco. In the San Luis Obispo region the non-marine Paso Robles beds, said to be 1000 ft. thick, belong to this period. Other local formations of
marine origin in California are those of San Diego and Wild Cat. In the Rocky Mountains these are lacustrine formations of considerable thickness, and certain conglomerates in Wyoming and Bishop Mountain are assigned to this age. The sands and clays with gypsum of Entre Rios in South America contain fossils of the Atlantic type.

Ligniteiferous shale with petroleum and great thickness of volcanic tuffs have been found in southern Sumatra. In New South Wales and the southern western district of South Australia there are coal beds, and in New Zealand glacial drift has left a deposit of cryoplanes and tillite beds near Mt. Plock. It has been found at elevations above present sea-level. Very similar deposits and volcanic rock, belonging to the Wanganui system of F. W. Hutton, are found in New Zealand.

The sea, while the broad valley of the Vistula has an elevation of only 130 to 150 ft. In the west (district of Lipno) broad terraces, covered with forests, small lakes and ponds, and very poor in vegetation, descend from the Baltic lake-district towards the plains of Plock; and in the central district of Mlawa extensive marshes fill the upper basin of the Wkrá. The Vistula borders the government on the south, almost all the way from Warsaw to Thorn, receiving the Skrwa and Wkrá. The Driwca, or Drewenz, flows along the north-west boundary, while several small tributaries of the Narew drain the north-eastern district of Ciechanow. Peat-bogs, used for fuel, and marshes containing bog-iron, fill many depressions in the north, while the more elevated parts of the plains are covered with fertile clays, or a kind of "black earth." Lacustrine post-glacial deposits fill all the depressions of the thick sheet of boulder clay, with Scandinavian erratic boulders, which extends everywhere over the Tertiary sands and marls—these last containing masses of silicated wood and lignite. Layers of gypsum are found in the hills beside the Vistula.

The estimated population in 1906 was 619,000. About one-third are Jews and 36,000 Germans. The government is divided into seven districts, of which the chief towns are Plock, Ciechanow, Lipno, Mlawa, Przasnysz, Rypin and Sierpc. Agriculture is the chief industry. The principal crops are rye, oats, barley, wheat and potatoes; beetroot is cultivated for sugar, especially on the large estates of the west, where modern machinery is used. Gardening and bee-keeping are extensively practised. In the north the property is much divided, and the landholders, very numerous in Ciechanow, are far from prosperous. The forests have been lavishly cut, but Plock is still one of the best wooded governments (20%) in Poland. Other occupations are provided by shipping on the Vistula, mining and various domestic industries, such as the fabrication of wooden cars, sledges and wheels, and textile industry. The manufactures include flour-mills, saw-mills, sugar factories, distilleries, tanneries, breweries,

See C. Reid, "The Pliocene Deposits of Britain" (Mem. Geol. Survey, 1890); T. E. Newton, "The Vertebrates of the Pliocene Deposits of Britain" (Mem. Geol. Survey, 1891) (both contain a bibliography); C. Reid, Origin of the British Flora (1899); and "Geological Literature" (Geol. Soc. London Annual, since 1893). (J. A. H.)

PLOKč, or PLOTSK, a government of Russian Poland, on the right bank of the Vistula, having the Prussian provinces of West and East Prussia on the N. and the Polish governments of Lomza on the E. and Warsaw on the S. Its area is 4160 sq. m. Its flat surface, 550 to 500 ft. above the sea-level, rises gently towards the north, where it merges into the Baltic coast-ridge of the Prussian lake district. Only a few hills reach 600 ft. above
agricultural implement works, match factories and ironworks. There is some export trade, especially in the Lipno district; but its development is hampered by lack of communications, the best being those offered by the Vistula. The railway from Warsaw to Danzig, via Ciechanow and Mlawa, serves the eastern part of the government.

After the second dismemberment of Poland in 1793, what is now the government of Plock became part of Prussia. It fell under Russian domination after the treaty of Vienna (1815), and, in the division of that time into five provinces, extended over the western part of the present government of Lomza, which was created in 1864 from the Ostródenka and Pultusk districts of Plock, together with parts of the province of Augustowo.

PLOEMEGER, a town of Russia, capital of the government of the same name, on the right bank of the Vistula 67 m. by the Vistula W.N.W. of Warsaw. Pop. 27,072. It has a cathedral, dating from the 12th century, but restored in 1903, which contains tombs of Polish dukes and of Kings Ladislaus and Boleslav (of the 11th and 12th centuries). There is considerable navigation on the Vistula, grain, flour, wool and beetroot being exported, while coal, petroleum, salt and fish are imported.

PLOEN, a town of Germany, in Schleswig-Holstein, beautifully situated between two lakes, the large and the small Ploener-See, 20 m. S. from Kiel by the railway to Eutin and Lubeck. Pop. (1903), 3735. It has a palace built about 1630 and now converted into a cadet school, a gymnasium and a botanical station. Tobacco, soap, soda, beer and furniture are manufactured, and there is a considerable trade in timber and grain. The lakes afford good fishing, and are navigated in summer by steamboats. Ploen is mentioned as early as the 11th century as a Wendish settlement, and a fortified place. It passed in 1559 to Duke John the Younger, founder of the line of Holstein-Sonderburg, on the extinction of which, in 1761, it fell to Denmark, and in 1867, with Schleswig-Holstein, to Prussia. The sons of the emperor William II. received their early education here. See H. Eggers, Schloss und Stadt Ploen (Kiel, 1877), and J. C. Kindler, Urkundenhandschrift (1877) (Plön, 1806). PLOENNES, LIUZE VON (1863-1872), German poet, was born at Hanau on the 7th of November 1803, the daughter of the naturalist Philipp Achilles Leisler. In 1824 she married the physician August von Ploennies in Darmstadt. After his death in 1847 she resided for some years in Belgium, then at Jugenheim on the Bergstrasse, but finally at Darmstadt, where she died on the 22nd of January 1872. Between 1844 and 1870 she published several volumes of verse, being particularly happy in ecletic love songs, patriotic poems and descriptions of scenery. She also wrote two biblical dramas, Maria Magdalena (1879) and David (1873).

As a translator from the English, Luise von Ploennies published two collections of poems, Britania (1843) and Englische Lyricer des 17. Jahrhunderts (1863), 3rd ed. (1867).

PLOERMEL, a town of western France, capital of an arrondissement in the department of Morbihan, 36 m. N.N.E. of Vannes by rail. Pop. (1900), 2492; commune, 5424. The Renaissance church of St. Arneol (16th century) is remarkable for the delicate carving of the north façade and for fine stained glass. It also possesses statues of John II. and John III., dukes of Brittany, which were transferred to the church from their tomb in an ancient Carmelite monastery founded in 1273 and destroyed by the Protestants in 1592 and again at the Revolution. The lower ecclesiastical seminary has an apartment in which the Estates of Brittany held several meetings. Remains of ramparts of the 12th century and some houses of the 16th century are also of interest. Farm-implements are manufactured, slate quarries are worked in the neighbourhood, and there is trade in cattle, wool, hemp, cloth, &c. Ploermel (Plou Armel, people of Armel) owes its name to Armeil, a hermit who lived in the district in the 6th century.

PLOESCI (Plezcei), the capital of the department of Prabova, Rumania; at the southern entrance of a valley among the Carpathian foothills, through which flows the river Prabova; and at the junction of railways to Buzau, Bucharest and Hermannstadt in Transylvania. Pop. (1900), 42,687. As the name Plesci (plezca, rainy) implies, the climate is moist. The surrounding hills are rich in petroleum, salt and lignite. There are cardboard factories, tanneries, and oil mills. Ploesci possesses schools of commerce and of arts and crafts, several banks, and many synagogues and churches, including the Orthodox church of St. Mary, built in 1740 by Matthew Bassarab.

PLOMBIÈRES, a town of eastern France, in the department of Voges, on a branch line of the Eastern railway, 17 m. S. E. Epinal by road. Pop. (1906), 1882. The town is situated at a height of 1410 ft. in a picturesque valley watered by the Auguronne. It is well known for its mineral springs, containing sulphuric and silicate acid, varying from 66° to 166° F. Plombières has a handsome modern church and a statue of the famous Louis Fragonard, and in the town the menhirs were utilized by the Romans and during the middle ages. In later times Montaigne, Richelieu, Stanislas, duke of Lorraine and Voltaire were among the distinguished people who visited the place. Napoleon III. built the most important of the bathing establishments and made other improvements.

PLOT, ROBERT (1640-1696), English naturalist and antiquary, was born at Borden in Kent in 1640. He was educated at Wye, and at Magdalen Hall, Oxford, where he graduated B.A. in 1661, and proceeded to M.A. (1664) and D.C.L. (1671). He was distinguished for his folio work The Natural History of Oxfordshire (1677), in which various fossils as well as other objects of interest, were figured and described. It was regarded as a model for many subsequent works. In 1677 Plot was elected F.R.S., and he was secretary for the Royal Society from 1682 to 1684. He was appointed in 1683 the first keeper of the Ashmolean Museum at Oxford, and in the same year he became professor of chemistry. In 1686 he wrote The Natural History of Staffordshire. Two years later he became historiographer-royal. He died on the 30th of April 1696.

PLOT, a term originally meaning a space of ground used for a specific purpose, especially as a building site, formally in frequent usage in the sense of a plan, a surveyed space of ground; hence also, in the literary sense of a plan or design. The word is of doubtful origin; there is a collateral form "plat," which appears in the 16th century, according to the New English Dictionary, under the influence of "plat," flat place, surface (fr. plat, Late Lat. plattus, probably from Gr. πλατός, broad). Skeat (Etym. Dict.) refers to "plot," in the sense of a space of ground, to the O. Eng. place, Mid. Eng. plack, later patch, patch. "Plot," in the sense of a plan, scheme, would then be identical with "plot," a conspiracy, which may be a shortened form of "complot," a French word, also of doubtful origin, meaning in the 12th century "a compact body of men;" in the 14th century "a conspiracy, a plot;" PLINITUS (A.D. 204-270), the most important representative of Neoplatonism, was born of Roman parents at Lycopeolus in Egypt. At Alexandria he attended the lectures of Ammonius Saccas (q.v.), the founder of the system, until 242, when he joined the Persian expedition of Gordian III., with the object of studying Persian and Indian philosophy on the spot. After the assassination of Gordian in 244, Plotinus was obliged to take refuge in Antioch, whence he made his way to Rome and set up as a teacher there. He soon attracted a large number of pupils, the most distinguished of whom were Amelius, Eustochius and Porphyry. The emperor Gallienus and his wife Salentina were also his enthusiastic admirers, and favoured his idea of founding a Platonic Commonwealth (Platonopolis) in Campania (cf. Bishop Berkeley’s scheme for the Bermuda islands), but the opposition of Gallienus’s counsellors and the death of Plotinus prevented the plan from being carried out. Plotinus’s wide popularity was due partly to the lucidity of his teaching, but perhaps even more to his strong personality. Asent developed into veneration; he was considered to be divinely inspired, and generally credited with miraculous powers. In spite of ill-health, he continued to teach and write until his death, which took place on the estate of one of his friends near Minturnae in Campania.
Under Ammonius Plotinus became imbued with the eclectic spirit of the Alexandrian school. Having accepted the Platonic metaphysical doctrine, he applied to it the Neo-Pythagorean principles and the Oriental doctrine of Emanation (q.v.). The results of this introspective mysticism were collected by him in a series of forty-five (originally forty-eight) treatises, arranged in six "Enneads," which constitute the most authoritative exposition of Neoplatonism. This arrangement is probably due to Porphyry, to whose editorial care they were consigned. There was also another ancient edition by Eustochius, but all the existing MSS. are based on Porphyry's edition.

The Enneads of Plotinus were first made known in the Latin translation of Marsilio Ficino (Florence, 1492) which was reprinted at Basle in 1550, with the Greek text of Petrus Perigenes, 1551, by J. F. Simon, i. (1845), and E. Vacherot (1846); A. Stirling, "Plotinus and Mendelssohn," 1853; A. Kirchhoff (1856), H. F. Müller (1878-1880), R. Volkmann (1883-1884). There is an English translation of selected portions by Thomas Taylor, re-edited in Bohn's Philosophical Library (1895, with introduction and bibliography by G. R. S. Mead).

On Plotinus generally see article in Suidas; Eunapius vitae sophistorum; and above all the Vita Plotini by his pupil Porphyry. Among modern works, see the treatises on the school of Alexandria by J. F. Simon, i. (1845), and E. Vacherot (1846); A. Stirling, "Plotinus and Mendelssohn," 1853; A. Kirchhoff (1856), H. F. Müller (1878-1880), R. Volkmann (1883-1884). There is an English translation of selected portions by Thomas Taylor, re-edited in Bohn's Philosophical Library (1895, with introduction and bibliography by G. R. S. Mead).

PLough AND PLoughing. To enable the soil to grow good crops the upper layer must be pulverized and weathered. This operation, performed in the garden by means of the spade, is carried on in the field on a larger scale by the plough,1 which breaks the soil and by inverting the furrow-slice, exposes fresh surfaces to the disintegrating influence of air, rain and frost.

The most primitive form of plough is found on the monuments of Egypt, where it is represented simply of a wooden wedge tipped with iron and fastened to a handle projecting backwards and a beam, pulled by men or oxen, projecting forwards. Many references to the plough are found in the Old Testament, notably that in 1 Sam. xiii. 20: "All the Israelites went down to the Philistines to sharpen every man his share and his coulters." Descriptions of ploughs found in Hesiod's Works and Days and in Virgil's Georgics i. 160-175, show little development in the implement. The same may be said of the Anglo-Saxon ploughs. These are shown with coultor and share and also with wheels, which had in earlier times been fitted to ploughs by the Greeks and also by the native Gauls. Pliny, H. N. xiii. 18, 15; A. Halle, Hist. Oeconom. (1897), E. Caird, Evolution of Theology in the Greek Philosophers (1904), i. 210-257; Rufus M. Jones, Studies in Mystical Religion (1909). A detailed account of Plotinus' philosophical system and an estimate of its importance with a careful analysis of the article Neoplatonism, the works above referred to, and the histories of philosophy. For his list of categories, see Categories; also Logos; Mysticism; Magic.

The working parts of the plough are the coultor, the share, and the mould-board or mould-board. These are carried on the beam, to which are attached the handles or iills at the back, and the hake or clevis and draught-chain at the front. The hake is notched at the bottom of the frame, and, by moving the draught-chain higher or lower thereon, the plough is caused to go more or less deeply into the ground. It may also be adjusted to suit the height of the horses used. The hake moves laterally on a quadrant and it is thus possible to give the plough a tendency to left or right by moving the hake in the reverse direction. A frame is bolted to the beam and this carries the breast or mould-board to the fore-end of which the share is fitted. The side-ap, a plate of iron fixed to the land-side of the frame, is intended to keep the edge of the unploughed soil vertical and prevent it from falling into the furrow. A piece of iron called the side is bolted to the bottom of the frame, and, running along the sole of the furrow, acts as a base to the whole implement. The coultor (either knife or disk) and sometimes a skim-coulter (or joiner) are attached adjustable to the beam, so as to act in the front of the share.

The coultor is a knife or revolving disk which is fixed so that its point clears the point of the share. The skim-coulter is shaped like a miniature plough, substituted for or fixed in front of the coultor; it is used chiefly on lea land, to pare off the surface of the soil together with the vegetation thereon, and turn it into the previous furrow, where it is immediately buried by the furrow slice. Two wheels of unequal height are commonly fitted to the front of the beam. By means of them the depth and width of the furrow are regulated, whereas in the case of "swing" or wheelless ploughs these points depend chiefly on the skill of the ploughman. In the wheeled plough some of the weight and downward pull due to its action on the ground is taken by the wheels; the sliding friction is thus to some extent converted into a rolling friction, and the draught is correspondingly diminished.

In operation the coultor makes a perpendicular cut separating the furrow-slice which is divided from the "sole" of the furrow by the share and then inverted by the curve of the breast as the plough moves forward. The process is indicated in the illustration of different types of furrow. The form of a furrow is
regulated by the shape and width of the share, working in combination with a proper shaped breast. A "crested" furrow is obtained by the use of a share, the wing of which is set at a higher altitude than the point, but this type of furrow is less generally found than the "rectangular" form obtained by a level-edged share, which leaves a flat bottom.

During the greater part of the 19th century the ideal of ploughing was to preserve the furrow-slice unbroken, and this object was attained by the use of long mould-boards which turned the slices gently and gradually, laying them over against one another at an angle of 45°, thus providing drainage at the bottom of the furrow, and exposing the greatest possible surface to the influences of the weather. Subsequently the digging plough came into vogue; the share being wider, a wider furrow is cut, while the slice is inverted by a short concave mould-board with a sharp turn which at the same time breaks up and pulverizes the soil after the fashion of a spade. Except on extremely heavy soils or on shallow soils with a subsoil which it is unwise to bring upon the surface, the modern tendency is in favour of the digging plough.

A ploughed field is divided into lands or sections of equal width separated by furrows. On light easy draining land 22 yds. is the usual width; on the heaviest lands it may be as little as 5 yds., and in the latter case the furrows will act as drains into which the water flows from the intervening ridges.1 Certain important variations of the ordinary plough demand consideration. The one-way plough lays the furrows alternately to its left and right, so that they all slope in the same direction. This is found advantageous on hill-sides where the work is easier if all the furrows are turned downhill; or from another point of view the furrows may be all laid uphill so as to counteract the tendency for the soil to work down the slope.

One-way ploughs also leave the land level and dispense with the wide open furrows between the ridges which are left by the ordinary plough. They are made on different principles. One type comprises two separate ploughs, one right hand and one left, which revolve on the beam, one working, while the other stands vertically above it. In another the mould-board and share are shaped so that they can be swung on a swivel under the beam when the latter is lifted. A third type is made on the "balance" principle, two plough beams with mould-boards being placed at right angles to one another, so that while the right-hand plough is at work the left-hand is elevated above the ground.

Double-furrow or multiple ploughs are a combination of two or more ploughs arranged in echelon so as to plough two or more furrows. The weight of these implements necessitates some provision for turning them at the headlands, and this is supplied either by a bowl wheel, enabling the plough to be turned on one side, or by a pair of wheels cranked so that they can be raised by a lever when the plough is working. The double-furrow plough was known as early as the 17th century, but, till the introduction of the latter device by Ransome in 1873, cannot be said to have been in successful use.

The "sulky" or riding plough is little known in the United Kingdom, but on the larger arable tracts of other countries where quick work is essential and the character of the surface permits, it is in general use. In this form of plough the frame is mounted on three wheels, one of which runs on the land, and the other two in the furrow. The furrow wheels are placed on inclined axles, the plough beam being carried on swing links, operated by a hand lever when it is necessary to raise the plough out of the furrow. The land wheel and the forward furrow wheel are adjustable vertically with reference to the frame, for the purpose of controlling the action of the plough.

In the disk plough, which is built both as a riding and a walking plough, the essential feature is the substitution of a concavo-

---

1 Methods of the "setting-out" of land to be ploughed together with a full discussion of other technical details relating to ploughing will be found in Ch. vii. of W. J. Malden's Workman's Technical Instructor (London, 1905).
convex disk, pivoted on the plough beam, for the mould-board and share of the ordinary plough. This disk is carried on an axle inclined to the line of draught, and also to a vertical plane. As the machine is drawn forward the disk revolves and cuts deeply into the ground, and by reason of its inclination crowds the earth outwards and thus turns a furrow. A scraper is provided to keep the disk clean and prevent sticking. The controlling levers and draught arrangements are similar to those in the "sulky" plough. The advantage of this plough over the ordinary form is in the absence of sliding friction, and in the mellow and porous condition in which it leaves the bottom of the furrow.

Disk ploughs are unsuitable for heavy sticky soils and for stony land, but may be used with effect on stubbles and on land in a dry hard state. Perhaps their most common use is in ploughing on a large scale in conjunction with steam power.

Steam is employed as motive power when it is necessary to plough large areas in a short time. In the United Kingdom steam ploughing is generally carried on on the double-engine system (introduced by Messrs. John Fowler about 1865), in which case two sets of ploughs are arranged on the one-way balance principle, so that while one set is at work the other is carried clear of the ground. In this arrangement, a pair of locomotive engines, each having a plain winding drum fixed underneath the boiler, are placed opposite to each other at the ends of the field to be operated upon; the rope of each of the engines is attached to the plough, or other tillage implement, which is drawn to and fro betwixt them by each working in turn. While the engine in gear is coiling in its rope and drawing the plough towards itself, the rope of the other engine is paid out with merely so much drag on it as to keep it from kinking or getting ravelled on the drum.

The sub-soil plough has the beam and body but not the mould-board of an ordinary plough. Following in the furrow of an ordinary plough it breaks through the sub-soil to a depth of several inches, making it porous and penetrable by plant roots.

Gripping and drawing ploughs are employed in opening the grips and trenches necessary both in surface and underground drainage.

See Davidson and Chase, *Farm Motors and Farm Machinery*; articles in *L. H. Bailey's Cyclopedia of American Agriculture* (New York, 1907) and *Smith Encyclopedia* (London, 1908), &c.

**PLOVER**, a bird whose name (Fr. *pluvier*, O. Fr. *plouver*) doubtless has its origin in the Latin *pluvia*, rain (as witness the German equivalent *Regenfeifer*, rain-fifer). P. Belon (1555) says that the name *Pluvier* is bestowed "pour ce qu'on le prend mieux en temps pluvieux qu'en nulle autre saison," which is not in accordance with modern observation, for in rainy weather plovers are wilder and harder to approach than in fine. Others have thought it is from the spotted (as though with rain-drops) upper plumage of two of the commonest species of plovers, to which the name especially belongs—the *Charadrius plumalis* of Linnaeus, or golden plover, and the *Squatarola helvetica* of recent ornithologists, or grey plover. Both these birds are very similar in general appearance, but the latter is the larger and has an aborted hind-toe on each foot. Its axillary feathers are also black, while in the golden plover they are pure white. The grey plover is a bird of almost circumpolar range, breeding in the far north of America, Asia and eastern Europe, frequenting in spring and autumn the coasts of the more temperate parts of each continent, and generally retiring farther southward in winter—examples not infrequently reaching Cape Colony, Ceylon, Australia and even Tasmania. *Charadrius plumalis* has a much narrower distribution, though where it occurs it is much more numerous. Its breeding quarters do not extend farther than from Iceland to western Siberia, but include the more elevated tracts in the British Islands, whence in autumn it spreads itself, often in immense flocks, over the cultivated districts if the fields be sufficiently open. Here some will remain for all the season of frost or snow permits, but the majority make for the Mediterranean basin, or the countries beyond, in which to winter; and stragglers find their way to the southern extremity of Africa. Two other cognate forms, *C. virgínus* and *C. futsus*, respectively represent *C. plumalis* in America and eastern Asia, where they are also known by the same English name. The discrimination of these two birds from one another requires a very acute eye, but both are easily distinguished from their European ally by their smaller size, their greyish-brown axillary feathers, and their proportionally longer and more slender legs. All, however—and the same is the case with the grey plover—undergo precisely the same seasonal

1 But for this really unimportant distinction both birds could doubtless have been kept by ornithologists in the same genus, for they agree in most other structural characters.

2 Schlegel (*Mus. Pays-Bas, Cartores*, p. 53) states that in some examples it seems impossible to determine the form to which they belong; but ordinarily American specimens are rather larger and stouter, and have shorter toes than those from Asia.
PLUCK—PLÜCKER

PLÜCKER, JULIUS (1801–1868), German mathematician and physicist, was born at Elberfeld on the 16th of June 1801. After being educated at Düsseldorf and at the universities of Bonn, Heidelberg and Berlin he went in 1823 to Paris, where he came under the influence of the great school of French geometers, whose founder, Gaspard Monge, was only recently dead. In 1825 he received his Privatdozent at Bonn, and after three years he was made professor extraordinary.

The title of his "habilitationsschrift," Geacrales analytischen applicationem ad eae quae geometriae altioris et mechanicae basis et fundamenta sunt e serie Tayloria deduci Julius Plücker (Bonn, 1824), indicated the course of his future researches. The mathematical influence of Monge had two sides represented respectively by his two great works, the Geometrie descriptive and the Application de l'analyse à la géométrie. Plücker aimed at furnishing modern geometry with suitable analytical methods so as to give it an independent analytical development. In this effort he was as successful as were his great contemporaries Poncelet and J. Steiner in cultivating the geometry in its purely synthetic form. From his lectures and researches at Bonn sprang his first great work, Analytisch-geometrische Entwickelungen (vol. i., 1828; vol. ii., 1831).

In the first volume of this treatise Plücker introduced for the first time the method of abridged notation which has become one of the characteristic features of modern analytical geometry (see GEOMETRY, ANALYTICAL). In the first volume of the Entwickelungen he applied the method of abridged notation to the straight line, circle and conic sections, and he subsequently used it with great effect in many of his researches, notably in his theory of cubic curves. In the second volume of the Entwickelungen he clearly established on a firm and independent basis the great principle of duality.

Another subject of importance which Plücker took up in the Entwickelungen was the curious paradox noticed by L. Euler and G. Cramer, that, when a certain number of the intersections of two algebraical curves are given, the rest are thereby determined. Euler had shown that when a number of the intersections of the curves of the $(p-q)$th degree lie on a curve of the $q$th degree the rest lie on a curve of the $q$th degree. Plücker finally (Gergonne Ann., 1828–1829) showed how many points must be taken on a curve of any degree so that curves of the same degree (homologous) may be drawn through them, and proved that all the points, beyond the given ones, in which these curves intersect the given one are formed in a particular and fixed manner. Later, simultaneously with C. G. J. Jacobi, he extended these results to curves and surfaces of unequal order.

Allied to the matter just mentioned was Plücker's discovery of the six equations connecting the numbers of singularities in algebraical curves (see CURVE). Plücker connected these results with the first place to Crelle's Journal (1834), vol. xii., and gave a further extension and complete account of his theory in his Theorie der algebraischen Curven (1839).

In 1833 Plücker left Bonn for Berlin, where he occupied a post in the Friedrich Wilhelm's Gymnasium. He was then called in 1834 as ordinary professor of mathematics to Halle. While there he published his System der analytischen Geometrie, auf neue Betrachtungsweisen gegründet, und insbesondere eine ausführliche Theorie der Curven dritter Ordnung entwoben (Berlin, 1835). In this work he introduced the use of linear functions in place of the ordinary co-ordinates; he also made the fullest use of the principles of collineation and reciprocity. His discussion of curves of the third order turned mainly on the nature of their asymptotes, and depended on the fact that the equation to every such curve can be put into the form $p\rho + \mu \varsigma = 0$. He gives a complete enumeration of them, including two hundred and nineteen species. In 1836 Plücker returned to Bonn as ordinary professor of mathematics. Here he published his Theorie der algebraischen Curven, which formed a continuation of the System der analytischen Geometrie. We must here pass over to the third of the titles: the asymptotes and singularities of algebraical curves respectively; and extensive use is made of the method of counting constants which plays so large a part in modern geometrical researches.

From this time Plücker's geometrical researches practically ceased, only to be resumed towards the end of his life. It is true that he published in 1846 his System der Geometrie des change of colour, greatly altering their appearance and equally affecting both sexes. In spring or early summer nearly the whole of the lower plumage from the chin to the vent, which during winter has been nearly pure white, becomes deep black. A corresponding alteration is at the same season observable in the upper plumage.

Though the birds just spoken of are those most emphatically entitled to be called plovers, the group of ringed plovers (see KILLDEER and LAPWING), with its allies, has, according to usage, hardly less claim to the name, which is also extended to some other more distant forms that can here have only the briefest notice. Among them one of the most remarkable is the "Zick-zack" (so-called from its cry)—the τορχικα of Herodotus (see HUMMING-BIRD), the Pluvianus or Hyas aegyptius of ornithologists, celebrated for the services it is said to render to the crocodiles—a small bird whose plumage of delicate lavender and cream colour is relieved by markings of black and white. This belongs to the small family Glareolidae, of which the members best known are the courser, Caranus, with some eight or ten species inhabiting the deserts of Africa and India, while one, C. gallicus, occasionally strays to Europe and even to England. Allied to them are the curious pratincoles (q.v.), also peculiar to the Old World, while the genera Thinocerus and Altius form an outlying group peculiar to South America, that is by some systematists regarded as a separate family Thinoceridae, near which are often placed the singular Sheathbills (q.v.). By most authorities the Stone-curlews (see CURLEW), the Oyster-catchers (q.v.) and Turnstones (q.v.) are also regarded as belonging to the family Charadridae, and some would add the Avocets (Recurvirostra) and Stilts (q.v.), among which the Caliver, or Crab-plover, Dromas ardeola—a form that has been banded about from one family and even order to another—should possibly find its resting-place. It frequents the sandy shores of the Indian Ocean and Bay of Bengal from Natal to Aden, and thence to Ceylon, the Malabar coast, and the Andaman and Nicobar Islands—a white and black bird, mounted on long legs, with webbed feet, and a bill so shaped as to have made some of the best ornithologists lodge it among the Terms (q.v.).

Though the various forms here spoken of as plovers are almost certainly closely allied, they must be regarded as constituting a very indefinite group, for hardly any strong line of demarcation can be drawn between them and the Sandpipers and Snipe-plovers. United, however, with both of the latter under the name of Limicola, after the method approved by the most recent systematists, the whole form an assemblage the compactness of which no observant ornithologist can hesitate to admit, even if he be uncertain of the exact kinship.

For "plovers' plumage" see LAPWING.

(A. N.)

PLUCK, to pull or pick off something, as flowers from a plant, feathers from a bird. The word in O. Eng. is pluckian or pleccian and is represented by numerous forms in Teutonic languages, cf. Ger. plücken, Du. plukken, Dan. plakke, etc. In sense and form a plausible identification has been found with It. piucare, to pick grapes, hair, feathers, cf. Fr. éplicher, pick. These Romanic words are to be referred to Lat. plius, hair, which has also given "peruke" or "perwig" and "plush." Difficulties of phonology, history and chronology, however, seem to show that this close similarity is only a coincidence. "Pluck," in the sense of courage, was originally a slang word of the price-ring, and Sir W. Scott (Journal, Sept. 4, 1837) speaks of the "want of that article blaguardly called pluck." In butcher's parlance the "pluck," of an animal is the heart, liver and lungs, probably so called from their being "plucked" or pulled out of the carcass immediately after slaughtering. The heart being the typical seat of courage, the transference is obvious. In university colloquial or slang use, "to pluck" is to refuse a candidate on examination; the more usual colloquial word is now "to plough." At the granting of degrees at Oxford objection to a candidate could be taken for other reasons than failure at examination, and the person thus challenging drew the attention of the proctor in congregation by "plucking" a piece of black silk attached to the back of his gown.
PLUM

Raumes in neuer analytischer Behandlungweise, but this contains merely a more systematic and polished rendering of his earlier results. In 1847 he was made professor of physics at Bonn; and from that time his scientific activity took a new and astonishing turn.

His first physical memoir, published in Poggendorff's Annalen (1847), vol. lxxii., contains his great discovery of magneto-electric action. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. In 1855 (Pogg. Ann. vol. cliii.) he published the first of his classical researches on the action of the magnet on the electric discharge in rarefied gases.

Plücker, first by himself and afterwards in conjunction with J. W. Hittorf, made many important discoveries in the spectroscopy of gases. He was the first to use the vacuum tube with the capillary part now called a Geissler's tube, by means of which the luminous intensity of feeble electric discharges was raised sufficiently to allow of spectroscopic investigation. He anticipated R. W. Y. Bunsen and G. Kirchhoff in announcing that the lines of the spectrum were characteristics of the chemical substance which emitted them, and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy.

Hittorf tells us that Plücker never attained great manual dexterity as an experimenter. He had always, however, very clear conceptions as to what was wanted, and possessed in a high degree the power of putting others in possession of his ideas and rendering them enthusiastic in carrying them into practice. Thus he was able to secure from the Siemens Hütte in 1846 the great electromagnet which he turned to such use in his magnetic researches; thus he attached to his service his former pupil the skilful mechanic Fessel; and thus he discovered and fully availed himself of the ability of the great glass-blower Geissler.

Induced by the encouragement of his mathematical friends in England, Plücker in 1865 returned to the field in which he first became famous, and adorned it by one more great achievement—the invention of what is now called "line geometry." His first memoir on the subject was published in the Philosophical Transactions of the Royal Society of London. It became the subject of much in which the new science was developed. Plücker himself worked out the theory of complexes of the first and second order, introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now so well known to the student of the higher mathematics. He was engaged in bringing out a large work embodying the results of his researches in line geometry when he died on the 22nd of May 1868. The work was so far advanced that his pupil and assistant Felix Klein was able to complete and publish it. (See Geometry, Line.) Among the very numerous honors bestowed on Plücker by the various scientific societies of Europe was the Copley medal, awarded to him by the Royal Society two years before his death.

PLUM, the English name both for certain kinds of tree and also generally for their fruit. The plum tree belongs to the genus Prunus, natural order Rosaceae. Cultivated plums are supposed to have originated from one or other of the species P. domestica (wild plum) or P. insititia (bullace). The young shoots of P. domestica are glabrous, and the fruit oblong; in P. insititia the young shoots are pubescent, and the fruit more or less glabrous. A third species, the common sloe or blackthorn, P. spinosa, has stout spines; its flowers expand before the leaves; and its fruit is very rough to the taste, in which particulars it differs from the two preceding. These distinctions, however, are not maintained with much constancy. P. domestica is a native of Anatolia and the Caucasus, and is considered to be the only species naturalized in Europe. P. insititia is wild in southern Europe, in Armenia, and along the shores of the Caspian. In the Swiss lake-dwellings stones of the P. insititia as well as of P. spinosa have been found, but not those of P. domestica. Nevertheless, the Romans cultivated large numbers of plums. They cultivated for most columns of numerous, some of the groups, such as the greengages, the damsons and the egg plums being very distinct, and sometimes reproducing themselves from seed. The colour of the fruit varies from green to deep purple, the size from that of a small cherry to that of a hen's egg; the form is oblong acute or obute at both ends, or globular; the stones or kernels vary in like manner; and the flavour, season of ripening and duration are all subject to variation. From its hardiness the plum is one of the most valuable fruit trees, as it is not particular as to soil, and the crop is less likely to be destroyed by spring frosts. Prunes and French plums are merely plums dried in the sun. Their preparation is carried on on a large scale in Bosnia and Servia, as well as in Spain, Portugal and southern France.

Plums are propagated chiefly by budding on stocks of the Mussel, Brussels, St Julien and Pear plums. The damson, wine-sour and other varieties, planted as standards, are generally increased by suckers. For planting against walls, trees which have been trained for two years in the nursery are preferred, but maiden trees can be very successfully introduced, and by liberal treatment may be speedily got to a fruiting state. Any good well-drained loamy soil is suitable for plums, that of medium quality as to lightness being decidedly preferable. Walls with an east or west aspect are generally allowed to them. The horizontal mode of training and the fan or half-fan forms are commonly followed; where there is sufficient height probably the fan system is the best. The shoots should be laid in nearly or quite at full length. The fruit is produced on small spurs on branches at least two years old, and the same spurs continue fruitful for several years. Standard plum trees should be planted 25 ft. apart each way, and dwarfs 15 or 20 ft. The latter are now largely grown for market purposes, being more easily supported when carrying heavy crops, fruiting earlier, and the fruit being gathered more easily from the dwarf bush than from standard trees.

The following is a selection of good varieties of plums, with their times of ripening—

**Diseases.**—The Plum is subject to several diseases of fungal origin, the widespread occurrence of the common plum or bladder-plums is due to an ascomycetous fungus, Exosascus pruni, the mycelium of which lives parasitically in the tissues of the host plant, passes into the ovary of the flower and causes the characteristic malformation of the fruit which becomes a deformed, sometimes curved or flattened, wrinkled dry structure, with a hollow occupying the place of the stone; the bladder plums are yellow at first, subsequently dingy red. The reproductive spores are borne in borne in (asci) which on a surface, appearing like a dot; they are scattered by the wind and propagate the disease. The only remedy is to cut off and burn the diseased branches.

Plum-leaf blister is caused by Polystigma trimorphum, a pyrenomycete fungus which forms thick shiny reddish patches on the leaves.
PLUMBAGO—PLUMBING

The reproductive spores are formed in embedded flesh-shaped receptacles (perithecia) and scattered after the leaves have fallen. The spots are not often so numerous as to do much harm to the leaves, but in more severe disease, infected leaves should be collected and burned. Soots and bird-cherry should be removed from the spot to prevent the spread of plumbago, as the various disease-producing insects and fungi live also on these species. The branches are sometimes attacked by weevils (Rhyncites) and the larvae of various moths, and saw-flies (chafly Eriocampa) in the leaves, and young branches and leaves are sometimes invaded by Aphides. Leaf-eating beetles and larvae of moths are best got rid of by shaking the branches and collecting the insects. Slug-worms or saw-fly larvae require treatment by washing with soapsuds, tobacco and lime-water or hellboore solution, and Aphides by syringing from below and removing all surplus young twigs.

PLUMBAGO (from Lat. Plumbum, lead), a name frequently applied to graphite (q.v.), in allusion to its resemblance to lead, whence it is popularly called "black-lead." It was formerly held in repute in medicine, but is now regarded as having no medicinal properties of any value.

PLUMBAGO DRAWINGS. What we should now speak of as pencil drawings were in the 17th and 18th centuries usually known as drawings "in plumbago," and there is a group of artists whose work is remarkable for their exquisite portraits drawn with finely pointed pieces of graphite and upon vellum. In some books of reference they are grouped as engravers, and as such Horace Walpole describes several of them. There is no doubt that many of their fine pencil drawings were prepared for the purpose of engraving, but this is not likely to have been the case with all, and we have evidence of certain commissions executed, by Forster, for example, when the portrait was not required for the preparation of a plate. One of the earliest of this group of workers was Simon Van de Pass (1595-1647), and in all probability his pencil drawings were either for reproduction on silver tablets or counters or for engraved plates. A very few pencil portraits by Abraham Bootingel, the Dutch engraver, have been preserved, which appear to have been first sketches, from which plates were afterwards engraved. They are of exceedingly delicate workmanship, and one in the present writer's collection is signed and dated. By David Loggan (1635-1700), a pupil of Van de Pass, there also remain a few portraits, as a rule drawn on vellum and executed with the utmost dexterity and with marvellous minuteness, the lines expressing the intricacies of a lace ruffle or the curls of a wig being perfectly rendered. It is evident that these were not always prepared for engraving, because there is one representing Charles II., set in a beautiful gold snuff box, which was given by the king to the duchess of Portsmouth and now belongs to the duke of Richmond, and a similar portrait of Cromwell in the possession of Lord Verulam, while several others belong to Lord Caledon, and there are no engravings corresponding to these. On the other hand, a large drawing by Loggan in the writer's collection, representing Charles II., is the sketch for the finished engraving and bears a declaration to that effect. An artist who is better known to the general collector is William Faithorne (1616-1601). He was the pupil of Sir Robert Peake, the engraver, but derived much of his skill from the time he spent with Nanteuil, whose involved style he closely followed, triumphing over technical difficulties with great success. There are important drawings by him in the Bodleian, at Welbeck Abbey and at Montagu House, and two fine portraits in the British Museum. Thomas Forster (fl. 1605-1712) was one of the greatest draughtsmen in this particular form of portraiture. His drawings are both on vellum and on paper, as a rule on vellum. Of the details of his life very little is known. Most of his engraved a few prints, but they are of the utmost rarity. His finest portraits are executed with very great refinement and delicacy, the modelling of the face being quite wonderful. It is in fact one of the marvels of this type of portraiture how such exquisite lines could have been drawn with the roughly cut pieces of graphite which were at the disposal of the artists. In some instances Forster's work the lines representing the modelling of the face are so fine as to be quite indistinguishable without the aid of a glass. His work can be studied at Welbeck Abbey, in the Holburne Museum at Bath, in the Victoria and Albert Museum, and at the British Museum. Some of the other portraits may be referred to, Robert and George White, father and son. The former (1645-1704) was a pupil of Loggan and a prolific engraver, and most of his drawings, executed on vellum, were for the purpose of engraving. George White (c. 1684-1732) was taught by his father, and finished some of his father's plates. His own pencil drawings are of even finer execution than those of Robert White. These three men, Forster and the two Whites, carefully signed their drawings and dated them. By Robert White there are remarkable portraits of Bunyan and Sir Matthew Hale in the British Museum, and his own portrait at Welbeck; and by John and his son, there are other drawings in private collections, depicting Sir Godfrey Kneller, Archbishop Tenison, and others. The two Fabers (1662-1721 and 1695-1756) were from Holland, the elder having been born at the Hague, as he himself states on his portrait which was in Vertue's collection. In addition to the portraits these two men usually added beautiful drawn inscriptions, often found within circles around the portraits and occasionally extending to many lines below them. The son was the greater artist and a famous mezzotinter. The portrait painter Jonathan Richardson (1665-1743) executed many fine drawings in pencil, examples of which can be seen in the British Museum. Some of these plumbago draughtsmen was a Scotsman, whose work is of the utmost rarity, David Paton, who worked in 1670. The chief of his drawings belong to the earl of Dysart and are at Ham House, and two examples of his portrait are in the possession of the Dalzell family. Of Paton's history nothing is known save that he was a Catholic who worked for more than one Dominic house, a devoted adherent of the Stuart cause, and was attached to the court of Charles II., when the king was in Scotland. At that time he drew his remarkable portrait of the king now at Ham House. There are drawings of the same character as his, the work of George Glover (d. 1678) and Thomas Cecil (fl. 1690), but the Museum of extraordiarily rarey affairs there were evidently first studies for engravings. Of Glover's work the only signed example known is in the writer's collection. A Swiss artist, Joseph Werner (b. 1637) or Waerner, drew well in pencil, adopting brown paper as the material upon which his best drawings were done, and in some cases heightening them with touches of white paint. The most notable of his portraits is one which is in the collection at Welbeck Abbey.

The earlier miniature painters also drew in this manner, notably Huberto de Francia, preparatory drawings for the jeweller's trade, and Isaac and Peter Oliver in portraits. By Isaac Oliver there is a fine drawing in Lord Derby's collection; and one by Peter, a marvellous likeness of Sir Bevil Grenville, in that of the writer. The latter men, Hone, Grimaldi, Lens and Downman, also drew finely in plumbago. Other notable exponents of this delightful art were Thomas Worlidge (1700-1766), F. Steele (c. 1714), W. Robins (c. 1730), G. A. Wolffram (1696-1775), George W. Webb (1664-1759), Johann von der Schulenburg (1733-1810), and the Swede, Charles Barckwits (1652-1745). Some were also resident in England for some years.

PLUMBING, properly working in lead (Lat. Plumbum), now a term embracing all work not only in lead, but also in tin, zinc and other metals, connected with the installation, fitting, repairing, soldering, &c., of pipes for water, gas, drainage, on cisterns, roofs and the like in any building, i.e. the general work of a plumber. (See BUILDING AND SEWERAGE.)
PLUMPTRE, EDWARD HAYES (1821-1891), English divine and scholar, was born in London on the 6th of August 1821. A scholar of University College, Oxford, he graduated with a double-first class in 1844, and in the same year he was elected fellow of Brasenose College. He was ordained in 1847, and shortly afterwards appointed chaplain, and the preacher of pastoral theology, at King's College, London. In 1863 he was given a prebendal stall at St Paul's, and from 1869 to 1874 he was a member of the committee appointed by Convocation to revise the authorized version of the Old Testament. He was Boyle lecturer in 1866-1867 ("Christ and Christendom"), and Grinfield lecturer on the Septuagint at Oxford 1872-1874.

After successively holding the livings of Pluckley and Brickley in Kent, he was installed in 1881 as dean of Wells. He died on the 1st of February 1891.

Plumptre was a man of great versatility, and attained high reputation as a translator of the plays of Sophocles (1865) and Aeschylus (1868), and of the Divina commedia of Dante (1886). In verse his main achievements were Lazarus (1864), and Master and Scholar (1866). Among his many theological works may be mentioned An Exposition of the Epistles to the Seven Churches of Asia (1877), The Spirits in Prison (1884), "The Book of Proverbs" (which he annotated in the Speaker's Commentary), the "Sapientia, Gospels, Acts, and II Corinthians," in Bishop Ellicott's New Testament Commentary, and Life of Bishop Ken (1888).

PLUNDER, to rob, to pillage, especially in war. The word came into English usage directly from Ger. Plündern (derived from a substantive Plünder meaning "household stuff," bedclothes, clothing, &c.), particularly with reference to the pillaging of the Thirty Years' War. Thomas May (History of the Long Parliament, 1647; quoted in the New English Dictionary) says: "Many Towns and Villages he [Prince Rupert] plundered, which is to say robb'd, for at that time first was the word plunder used in England, being borne in Germany." The New English Dictionary's earliest quotation is from the Swedish Intelligencer (1650).

PLUNKET, OLIVER (1629-1681), Irish Roman Catholic divine, was born at Loughcrew, Co. Meath. He was educated privately and at Rome, whither he went with Father Scarampi in 1645. From 1657 to 1660 he was professor of theology at the College of the Propaganda, enjoyed the friendship of the historian, Pallavicini, and acted as representative of Irish ecclesiastical affairs at Rome. Pope Clement IX appointed him to the archbishopric of Armagh and primate of Ireland in July 1660, and in November he was consecrated at Ghent, reaching Ireland in March 1670. Lord Berkeley of Stratton, the viceroy, showed him much hospitality and allowed him to establish a Jesuit school in Dublin. Plunket showed amazing diligence in furthering the cause of his Church. He was in very straitened circumstances, the revenue of his see being only 621 in good years. The repressive measures following on the Test Act bore hardly upon him, and in December 1678 he was imprisoned in Dublin Castle for six weeks. Accused of a share in the Irish branch of the "Popish Plot," he was brought to London, and in June 1681 arraigned in the King's Bench, charged with conspiring to bring a French army to Carlingford. He made a good defence, but on the absurdity of evidence the jury convicted him of treason, and on the 1st of July he was hanged, drawn and quartered.

PLUNKET, WILLIAM CONYNHAM PLUNKET, 1ST BARON (1764-1854), Irish lawyer, orator and statesman, was born in the county of Fermanagh in July 1764. 1 He was educated first by his father, a Presbyterian minister of considerable ability and reputation, and in 1779 he became a student of Trinity College, Dublin. He was conspicuous as the acknowledged leader of the Historical Society, the debating club of Trinity College, then full of young men of remarkable promise. Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. He gradually obtained a considerable practice in equity; and was made a king's counsel in 1797.

The Irish Plunkets are distinguished by the spelling of the name from the Plunketts of the families of the barons Dunany (cr. 1439) and the earls of Fingall (cr. 1628), though the earlier members of these houses are often given the spelling of Plunket.

In 1796 he entered the Irish parliament as member for Charleton. He was an anti-Jacobin Whig of the school of Burke, not ungraciously filled with a fervent Irish patriotism. But he was also where admirer of the constitutional government of England as established in 1688; he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was the only reform he sought for his country; he opposed the union because he thought it incompatible with this object.

When Plunket entered the Irish parliament, the Irish Whig party was almost extinct, and Pitt was leading his way to accomplish the union. In this he was seconded ably by Lord Castlereagh, by his policy caused by a wild insurrection, and by the secession of Grattan from politics. When, however, the measure was brought forward, among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognized. His speeches raised him immediately to the front rank of his party; and when Grattan re-entered the moribund senate he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803, after Emmet's rebellion, he was selected as one of the Crown lawyers to prosecute the unfortunate enthusiast, and at the trial, in summing up the evidence, delivered a speech of remarkable power, which shows his characteristic dislike of revolutionary outbreaks. For this speech he was exposed to much unmerited obloquy, and more especially to the abuse of Cobbett, against whom he brought a successful action for damages.

In 1803, in Pitt's second administration, he became solicitor-general, and in 1805 attorney-general for Ireland; and he continued in office when Lord Grenville came into power in 1806. Plunket held a seat in the Imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but when the Grenville cabinet was dissolved he returned once more to professional life.

In 1812, having amassed a considerable fortune, he re-entered parliament as member for Trinity College, and identified himself with the Grenviclle or anti-Gallican Whigs. He was soon acknowledged as one of the first orators, if not the first, of the House of Commons. His reverence for the English constitution in church and state, his steady advocacy of the war with Napoleon, and his antipathy to anything like democracy made him popular with the Tory party. In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "Bottle Riot," an attempt on his part to put down the Orange faction in Ireland. He strenuously opposed the Catholic Association, which about this time, under the guidance of O'Connell, began its agitation. In 1825 he made a powerful speech against it; thus the curious spectacle was seen of the ablest champion of an oppressed church doing all in his power to check its efforts to emancipate itself.

In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who regarded an Irishman as an intruder, he resigned in a few days. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. He died on the 4th of January 1854, and was succeeded by his eldest son, the bishop of Tuam (1792-1866) as 2nd baron. The 4th baron (1828-1897) was bishop of Meath and afterwards archbishop of Dublin and primate of Ireland, and an active ecclesiastical statesman; and his younger brother David Plunket (b. 1838), solicitor-general for Ireland in 1875-1877, and first commissioner of works in the Unionist administration of 1885-1892, was in 1895 created Baron
Rathmore. William Lee Plunkett, 5th baron (b. 1864), was governor of New Zealand from 1904 to 1910.

PLUNKETT, SIR HORACE CURZON (1854–1907), Irish politician, third son of Edward, 16th baron Dunsany, was born on the 24th of October 1854, and was educated at Eton and University College, Oxford, of which college he became honorary fellow in 1900. He spent ten years (1879–1889) ranching in Montana, U.S.A., where, together with a substantial fortune, he acquired experience that proved invaluable in the work of agricultural education, improvement and development, to which he devoted himself on his return to Ireland in 1889. At first Plunkett resolved to hold himself aloof from party politics, and he set himself to bring together men of all political views for the advancement of the prosperity of the Irish people. In 1894 he founded the Irish Agricultural Organization Society, which accomplished a work of incalculable importance by introducing co-operation among Irish farmers, and by proving to the latter the benefits obtainable through more economical and efficient management. But already in 1892 he had felt compelled to abandon his non-political attitude, and he entered parliament as Unionist member for south Dublin (county). Continuing, however, his policy of conciliation, Plunkett suggested in August 1893 that a few prominent persons of various political opinions should meet to discuss and frame a scheme of practical legislation. The outcome of this proposal was the formation of the “Recess Committee” with Plunkett as chairman, which included men of such divergent views as the earl of Mayo, Mr John Redmond, The O’Conor Don and Mr Thomas Sinclair. In July 1896 the Recess Committee issued a report, of which Plunkett was the author, containing valuable accounts of the systems of state aid to agriculture and of technical instruction in foreign countries. This report, and the growing influence of Plunkett, who became a member of the Irish Privy Council in 1897, led to the passing of an act in 1899 which established a department of agriculture and technical instruction in Ireland, of which the chief secretary was to be president ex officio. Plunkett was appointed vice-president, a position which gave him control of the department’s operations. It was intended that the vice-president should be responsible for the department in the House of Commons, but at the general election of 1900 Plunkett lost his seat. An extensively signed memorial, supported by the Agricultural Council, prayed that he might not be removed from office, and at the government’s request he continued to direct the policy of the department without a seat in parliament. He was created K.C.V.O. in 1903.

On the accession of the Liberal party to power in 1906, Sir Horace Plunkett was requested by Mr Bryce, the new chief secretary, to remain at the head of the department created in 1899; in the House of Commons as a Unionist, Plunkett had incurred the hostility of the Nationalist party, whose resentment had been further excited by the bold statement of certain unpardonable truths in his book, Ireland in the New Century (1904), in which he described the economic condition and needs of the country and the nature of the agricultural improvement schemes he had inaugurated. A determined effort was therefore made by the Nationalists to drive from office the man who had probably done more than any one else of his generation to benefit the Irish people; and in moving a resolution in the House of Commons with this object in 1907, a Nationalist declared that his party “took their stand on the principle that the industrial revival could only go hand in hand with the national movement.” The government gave way, and in the summer of 1907 Sir Horace Plunkett retired from office. Since the year 1900 a grant of about £10,000 had been made annually by the Department of Agriculture to the Irish Agricultural Organization Society; but the new vice-president, Mr T. W. Russell, who had been himself previously a member of the Unionist administration, withdrew in 1907 this modest support of an association with which Sir Horace Plunkett was so closely identified, and of which he continued to be the guiding spirit. In addition to the publication mentioned, Sir Horace Plunkett published Noblesse Oblige: An Irish Rendering (1908), and Rural Life Problems of the United States (1910).

PLURALISM (Lat. plus, plus, many, several), a term used generally in the sense of plurality (see below), and in philosophy for any theory which postulates more than one absolutely distinct being or principle of being, opposed to monism. Pluralistic systems are based on the difficulty of reconciling with the monistic principle the principles of variety and freewill. The chief difficulty which besets any such view is that if the elements are absolutely independent, the cosmos disappears and we are left with chaos: if, on the other hand, there is interrelation (or Plutarch’s system), the elements are not ultimate in any intelligible sense.

PLURALITY (O. Fr. pluralité, Late Lat. pluralitas, plural number), in a general sense, a word denoting more than one; applied particularly to the holding of two or more offices by the same person (called then a pluralist). In ecclesiastical law, plurality or the holding of more than one benefice or prelacy was always discountenanced, and is now prohibited in England by the Plurals Act 1838, as amended by the Plurals Act 1850 and the Pluralities Acts Amendment Act 1885. By the latter act a provision was made that two benefices might be held together, by appointment of the archbishop on the recommendation of the bishop, if the churches be within four miles of each other, and if the annual value of one does not exceed £200 (see Benefice). It was formerly a practice to evade enactments against plurality by means of commendams, i.e. by committing or commending a benefice to a holder of other benefices until an incumbent should be provided for it. Commandams were abolished by the Ecclesiastical Commissioners Act 1836 (6 & 7 Will. IV. c. 77, § 18). See also Coll v. Bishop of Coventry, 1613, Hob. 126 seq., where much learning on the subject will be found.

In elections, particularly where there are three or more candidates, and no one candidate receives an absolute majority of votes, the excess of votes polled by the first candidate over the second is often termed plurality, especially in the United States.

PLUSH (Fr. peluche), a textile fabric having a cut nap or pile the same as fustian or velvet. Originally the pile of plush consisted of mohair or worsted yarn, but now silk by itself or with a cotton backing is used for plush, the distinction from velvet being found in the longer and less dense pile of plush. The material is largely used for upholstery and furniture purposes, and is also much employed in dress and millinery.

PLUTARCH (Gr. Ploutarchos) (c. A.D. 46–120). Greek biographer and miscellaneous writer, was born at Chaeronea in Boeotia. After having been trained in philosophy at Athens he travelled and stayed some time at Rome, where he lectured on philosophy and undertook the education of Hadrian.1 Trajan bestowed consular rank upon him, and Hadrian appointed him procurator of Greece. He died in his native town, where he was archon and priest of the Pythian Apollo. In the Consolation to his Wife on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch’s brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent of any particular school of philosophy. His vast acquaintance with the literature of his time is everywhere apparent.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his forty-six Parallel Lives. He is thought to have written this work in his later years after his return to Chaeronea. His knowledge of Latin and of Roman history he must have partly derived from some years’ residence in Rome and other

1 There seems no authority for this statement earlier than the middle ages.
On the Right Way of Hearing (σπουδαία έσκ�ευσις) advocates the listening in silence to what is being said, and our principle is to reply to statements which may yet receive some addition or modification from the speaker (§ 4). The hearer is not to give too much weight to the style, manner or tone of the speaker (§ 7), not to be too apt to be too prodigal of praises, not to be impatient if he hears faults reprobated by the lecturer (§ 16). He concludes with the maxim, "to hear rightly is the beginning of living rightly," though it has in view throughout his own profession as a lecturer.

How a Flatterer may be Distinguished from a Friend is a rather long and uninteresting treatise. The ancient writers are full of reflections against flatterers who do not seem to exercise much influence in modern society. The really dangerous flatterer (§ 4) is not the parasite, but the pretender to a disinterested friendship—one who affects similar tastes, and so insinuates himself into your confidence. Your faults are passed over in silence, flattery is poured in, but flattery as, when he occupies a good seat at a public meeting for the express purpose of resigning it to his patron (§ 15). A true friend, on the contrary, speaks freely on proper occasions. The whole point of the discussion is to draw the writer's attention to the distinction of opinion. The citations, which are fairly numerous, are mostly from Homer.

How one may be Conscious of Progress in Goodness is addressed to Sosius Senecio, who was consul in the last years of Nero, and more than once (99, 102, 107) under Trajan. If, says Plutarch, a man could become suddenly wise instead of foolish, he could not be ignorant of the change. So the problem is, how to reform one's mental processes. Gradual advance in virtue is like steady sailing on a wide sea, and can only be measured by the time taken and the forces applied (§ 3). Zero test double by dreams (§ 12); if no excess of their number suggests the impression that an obnoxious influence had been purged by reason and philosophy. When we love the truly good, and adapt ourselves to their looks and manners, and this even with the loss of worldly prosperity, then we are really wise. With advice such as this, little sins is a evidence of a scrupulous conscience (§ 17).

How to get Benefit out of Enemies argues that, as primitive man had savage animals to fight against, but learnt to use their skins for clothing and their flesh for food, so we are bound to use even our enemies to some good purpose. One service they do to us is to make us live warily against plots; another is, they induce us to our advantage, so as to enable us to despatch them, but by making them secretly jealous of us (§ 4). Another, the thought that leads us to consider if we are ourselves faulst, and to be found fault with by a foe is likely to be plain truth speaking, διόταν ὑμεῖς ἴστατεν ἑαυτοῖς (§ 5). How natural man, are diverted from our friends by being legitiably expended on our enemies (§ 10).

On Having Many Friends, On Chance, On Virtue and Vice, are three short essays, the first advocating the concentration of one's affections on a few who are worthy (τῶν ἄλλων φιλίᾳ διόταν, § 4), rather than diluting them, as it were, on the many; the second plead that intelligence, φορεύς, not mere luck, is the ruling passion; and the third, that all such friends are good in their own way, but other names for happiness and misery. All these are interspersed with citations from the poets, several of them unknown from other sources.

A longer treatise, well and clearly written, and not less valuable for its many quotations, is the Consolation addressed to Apollonius (considered surpising by some) on the early death of his "generally beloved and religious and dutiful son." Equality of mind both in prosperity and in adversity is recommended (§ 2), but such names as "ups and downs" (ὕπαι πάντων) in life, where there are storms and calms on the sea, and good and bad seasons on the earth. That to reverse this he illustrates by citing fifteen fine verses from Menander (§ 5). The uselessness of indulging in grief is pointed out, death being a debt to all and not to be regarded as an evil (§§ 10-12). Plato's doctrine is cited (§ 13) that the body is a barden and an enemy to the soul; to the soul may be added (§ 14) that the body are in the same category as the unicorn (§ 15). The lamenting a death because it is untimely or premature has something of selfishness in it (§ 16), besides that it only means that one has arrived sooner than another at the end of a collision journey. It is more grievous because it is untimely, a new-born infant's death would be the most grievous of all (§ 23). One who has died early may have been spared many woes rather than have been deprived of many blessings; and the author would have the gods when they ask for it (§ 28). Examples are given of fortitude and resignation under such affliction (§ 33). If, says the author, you can be resigned even for the good, better, be sure that such a son will have a place in heaven. The author has borrowed from the Νῦν νεωτος of Crantor.

Precepts about Wealth commences as a dialogue, and extends to some length. Some precepts are a little trivial: "Poverty is a blessing;" others are obscure, and contains but little that falls in with modern ideas. Milk, he says, should be taken for food rather than for drink, and wine should not be indulged in after hard work or mental effort, for it tends to increase the body's necessity; if a drunk, than purges or emetics is a temperate diet, which induces, the bodi
functions to act of themselves (§ 26). Another wise saying is that idleness does not conduce to health (όδος ἀθλητικής καὶ μὲν ἄθλο υγιές ᥏ρεῖται) (§ 26), and yet another that a man should learn by his body capabilities without always consulting a physician (§ 26).

Advice to the Married is addressed to his newly wedded friends Plutarch and Priscus. It is plain and written, and consists chiefly of short maxims and anecdotes, with but few citations from the poets.

The Banquet of the Seven Wise Men (considered spurious by some) is accounted as the severest of the several of the Platonic Symposium, with conversations that have come down to us. It is supposed to be given by Periander in the public banquet-room (ἐκκαθόρισμος) near the haedron of Corinth (Lechaeum) on the occasion of a sacrifice to Apollo. There were seven friends of the principal guests being also present. Like Plato’s Symposium this treatise takes the form of a narrative of what was said by a director or host being one Diccles, a friend of Periander, who promises to give Nicarchus, the narrator, its use and presence.

The dinner was simple, and in contrast with the usual splendour of "tyrants" (§ 4). The conversation turns on variants being more or less composed of the essence of the five elements, fire, ether, earth, air and water (§ 37). The whole treatise is metaphysical, but it concludes with remarks on the exhalations at Delphi having different effects on different people and at different times. The whole is a speculation, this being the breath of some mysterious being sent up from the under-world.

On the Pythian Responses, why not longer given in Verse, is also a dialogue in design, which is continued and anecdotes about the statues and other offerings at Delphi. It is rather an amusing essay, and may be regarded as a kind of appendix to the last. The theory propounded (§ 29) is that verse was the earlier vehicle of philosophy, history and religion, but that plain prose has become the later fashion, and therefore that oracles are now generally delivered "in the same form as laws speak to citizens, kings reply to their subjects, and scholars bear their teachers speec". The chorus of that sort was brought about in the verse, as the facility with which it was employed by impostors (§ 25). Moreover, verse is better suited to ambiguity, and oracles nowadays have less need to be ambiguous (§ 88).

On Chidren, is a treatise in inquiry why that letter or symbol was written on or in the Delphic temple. Some thought it represented the number five, others that it introduced the inquiry of oracles, seeing, if it had so to be done, while one of the speakers, Arnomen of Apollonia, advised to ask an oracle in Apollonia containing the predication of existence (§ 17).

On the Face of the Moon's Disk is a long and curious if somewhat trifling speculation, yet not without interest from its calculations of the sizes and the distance from earth of the sun and moon (§ 10), and from the contrast between ancient lunar theories and modern mathematics. The cause of the moon’s light, its peculiar colour, the distance of its shadow, the use of its position, the effects of its phases are discussed in this dialogue, the beginning and end of which are alike abrupt. Some of the "guesses at truth" are very near the mark, such as when it is suggested (§§ 21–22) that the moon, like the earth, contains deep cavities, and that the "moon" and its "face" is nothing but the shadows of streams or of deep ravines.

On the Delphic Vows is a dialogue consequent on a supposed lecture by Epictetus. An objection is raised to the ordinary dealings of providence, that long-delayed punishment encourages the sinner and disappoints the injured, the reply to which is that the end of judgment is not in the present, and that the more the sins of the last day shall be, and the longer the longer life the greater is the share of misery (§ 9). The essay concludes with a long story about one Theopseus, and his treatment which he saw, during a trance, of the souls in the other world.

On Fate (probably spurious) discusses the law of chance as against the overruling of providence. This treatise ends abruptly; the point is not unlike the style of Atheneus and providence have their due influence in mundane affairs (§ 9), and that all things are constituted for the best.

On the Genius of the Dead is a long essay, and, like so many of the rest, is founded on a treatise of a dialogical character. The character of the genius, and his supernatural visions in the cave of Trophonius, are related at length in the Platonic style (§ 22), and the true nature of the delusions is revealed to them. They are the souls of the just, who still retain regard for humanity, and use their godly efforts after virtue (§ 28). The dialogue ends with an interesting narrative of the concealment of Pelopidas and some of the Thracian conspirators against the Spartans in the siege of Leucas.

On Exile is a fine essay, rendered the more interesting from its numerous quotations from the poets, including several from the Phoenician. Man is not a plant that grows only in one soil; he belongs to heaven rather than to earth, and wherever he goes he is the same as the sun, the same seasons, the same providence, the same laws of virtue and justice (§ 5). There is no discredit in being driven from one's country; Apollo himself was banished from heaven and condemned to live for ever in Hades.

The Consolation to His Wife, on the early death of their only daughter Timoxena (§ 7), is a feeling and sensible exhortation to marry another of Chilón of Athens.

Nine books of Symposiaci extend to a great length, discussing inquiries (ῥητορικα) on a vast number of subjects. The general treatment of these, in which great literary knowledge is displayed, is unlike the style of Atheneus and providence have their due influence in mundane affairs (§ 9).

The Amorous Man is a dialogue of some length, describing a conversation on the nature of love held at Helicon, pending a quinquennial feast of the Thespians, who specially worshipped that deity in their temple. The Muse of Delphi is held in high estimation.

In § 24 mention is made of the emperor Vespasian. It is followed by a short treatise entitled Love Stories, giving a few narratives of sensational adventures of lovers.

A shorter treatise is dedicated to Tejan, extend to a great length, and are divided into three parts: (1) of kings and commanders (including many Roman); (2) of Spartans; (3) of Spartan women (a short treatise on Spartan institutions being interspersed between the last two). The names of the authors are added, and some of them a large number of maxims are attributed.

A rather long treatise On the Virtues of Women contains a series of narratives of noble deeds done by the sex in times of danger and trouble, especially in war. Many of the stories are interesting, and the style is easy and good.

Another long and learned work bears the rather obscure title Kýklos τῶν ἐραστῶν, mainly since the authors are clearly wrong.

On the Romans and Graecae, in two parts. In the former, which contains one hundred and thirteen headings, the inquiry (on some matter political, religious or antiquarian) always commences with ἐκ τῆς ἑλληνικῆς ἡσυχίας, and closes with διὰ τῆς ἑλληνικῆς ἡσυχίας, with alternative explanations. In the Greek Questions the form of inquiry is more often ἐπὶ τῶν ἀρχαίων, not followed by τῶν ἑλληνικῶν. This treatise is of great interest and importance to classical archaeology, though the inquiries seem occasionally taken from the authors of the Graecae.

Parallels (spurious) are a series of similar incidents which occurred respectively to Greeks and Romans, the Greek standing first and the Roman counterpart following. Many of the characters are mythological though Plutarch gives them their usual names.

On the Fortune of the Romans discusses whether, on the whole, good luck or valour had more influence in giving the Romans the supremacy. This is followed by two discourses on the same question, each amplified by a long and a short treatise.

Alcibiades' career is the subject of two treatises. Whether the Athenians were more renowned for War or for Wisdom? The conclusion is (§ 7) that it was not so much by the fame of their poets as by the deeds of their heroes that Athens became renowned.
Plutarch—Pluto

Gryllus is a most amusing dialogue, in which Circe, Odysseus and a talking pig take part. Odysseus wishes that all the human beings that have been changed by the sorceress into bestial forms should be restored; but the pig argues that in moral virtues, such as true beauty, chastity, temperance, and generosité, complicity of life and contentment, animals are very far superior to man. Whether Land Animals or Water Animals are the Cleverst is a rather facile view of the abilities of the spiders, dogs, &c., on the one hand, and the crocodile, the dolphin, the tunny and many kinds of fish, on the other. This is a good essay, much in the style of Aristotle's History of Animals.

Plutarch concludes with an observation on the origin of the practice, viz. necessity, and makes a touching appeal to man not to destroy life for mere gluttony (§ 4). This is a short but very sensible and interesting argument. Questions on Plato are ten in number, mainly on the division of animals; the subjects are the latter. The essay is not long, but it concerns Platonists only. Whether Water or Fire is more Useful is also short; after discussing the uses of both elements it decides in favour of the latter, since nothing can exceed in importance the warmth of life and the light of the sun. On Primary Cold is a physical speculation on the true nature and origin of the quality antithetical to heat. Physical Reasons (Questiones Naturales) are replies to inquiries as to why certain facts or phenomena occur, e.g. "Why is salt the only flavour not in fruits?" "Why do fishing-nets rot in winter more than in summer?" "Why does the oil on the sea surface froth?" "On the Opinions accepted by the Philosophers (spiruous), in five books, is a valuable compendium of the views of the Ionic school and the Stoics on the phenomena of the universe and of life. On the Ill-nature of Ierodatus is a pitiless piece of vindictiveness; the historian is asked to give an account to the Boeotians and Laconians, but to the Corinthians and other Greek states. It is easy to say that this essay "neither requires nor merits refutation"; but Plutarch knew history, and he will not allow the contemporary editor of the Classics to go unpunished. The choice of friends, and the caution against enmities, the dangers of love, of gain and of ambition, with many topics of the like kind, are sensibly advanced and illustrated by examples.

Bibliography.—Editio princeps, by H. Stephanus (1772); other complete editions by J. J. Reiske (1774-1782), J. G. Hutton (1791-1804), J. Döhner and F. Döbener (1845-1855). Of the Lives, there are numerous translations into English (1889-1891), and of many separate lives by Siebert-Blass, Sinensis-Fuhr, Holden, Hardy and others. There are many English translations of Essays; the best known is that by John and William Langhorne; also the old French translation by Jacques Aymonier (1684-1685), from which Sir Thomas North's (1759) was made, newly edited by G. Wyndham (1805); many of the Roman lives have been translated into English by W. Ellis (1794), by W. Wynterbach (1795-1830), and G. N. Bernadakies (1888-1896). The old English translation by Philemon Holland (1603) has been revised by C. W. King and A. R. Shilleto in Bohn's Classical Library (1868-1888), and a later translation by various hands (London, 1684-1694), edited by W. W. Goodwin with introduction by R. W. Emerson, has been republished at Cambridge, Massachusetts (1874-1875). Mention may also be made of P. Holland's Romane Questions, essays and sermons (London, 1589-1591), and various transcriptions of Rhetoricae Problematum, with essays on "Roman Worship and Belief," by G. C. Allen (1904); De la Musique, ed. H. Weil and Th. Reinach (1906); J. Oakesmith, The Religion of Plutarch as expounded in his Ethes (London, 1898); P. de Morgan, L'Eglise et la Morale de Plutarque (1873); O. Gréard, De la Morale de Plutarque (1866); R. Volkman, Leben, Schriften und Philosophie des Plutarch (1869). The earlier literature of Plutarch is very extensive, for which W. Engemann, Scriptores graeci (1881-1888) may be consulted.

Plutarch, of Athens (c. 350–430), Greek philosopher, head of the Neoplatonist school at Athens at the beginning of the 5th century, was the son of Nestorius and father of Hierius and Asclepiogenes, who were his colleagues at the school. The origin of Neoplatonism in Athens is not known, but Plutarch and his followers (the "Platonic Succession") claim to be the disciples of Iamblichus, and through him of Porphyry and Plotinus. Plutarch's main principle was that the study of Aristotle must precede that of Plato, and that the student should be taught to realize primarily the fundamental points of agreement between them. With this object he wrote a commentary on the De anima which was the most important contribution to Aristotelian literature since the time of Alexander of Aphrodisias. His example was followed by Syrius and others of the school. This critical spirit reached its greatest height in Proclus, the ablest exponent of this latter-day syncretism. Plutarch was versed in all the theurgic traditions of the school, and believed in the possibility of attaining to communion with the Deity by the medium of the theurgic rites. Unlike the Alexandrians and the early Renaissance writers, he maintained that the soul which is bound up in the body by the ties of imagination and sensation does not perish with the corporeal media of sensation. In psychology, while believing that Reason is the basis and foundation of all consciousness, he interposed between sensation and thought the faculty of Imagination, which, as distinct from both, is the activity of the soul under the stimulus of unceasing sensation. In other words, it provides the raw material for the operation of Reason. Reason is present in children as an inoperative potentiality, in adults as working upon the data of sensation and imagination, and, in its pure activity, it is the transcendental or pure intelligence of God.

Pluto (πλοῦτος), in Greek mythology, the god of the lower world. His oldest name was Hades, Aldeus or Aldeounes, "the Unseen." He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions. The last, afterwards known as Hades from their ruler, fell to Pluto. Here he ruled with his wife Persephone over the other powers below and over the dead. He is stern and pitiless, deaf to prayer or flattery, and sacrifice to him is of no avail; only the music of Orpheus prevailed upon him to restore his wife Eurydice. His helmet, given him by the Cyclopes after their release from Tartarus, rendered him invisible (like the Tartar's) at the type of German mythology. He is hated and feared by gods and men, who, afraid to utter his name, both in daily life and on solemn occasions make use of euphemistic epithets: Polydeuctes (the receiver of many), Clymenus (the Illustrious), Eubulus (the giver of good counsel). Later, owing to his connexion with Persephone and under the influence of the Eleusinian mysteries, the idea of his character underwent a radical change. Instead of the life-hating god of death, he became a beneficent god, the bestower of grain, minerals, and other blessings produced in the depths of the earth. In this aspect he was called Pluto, the "giver of wealth" (a name that first occurs in the Attic poets of the 5th century), and at most of the centres of his cult he was so worshipped; at Elis alone he was Hades, the god of the dead. The plants sacred to him were the cypress and narcissus; black victims were sacrificed to him, not white, like those offered to the other gods. In art he was represented like Zeus and Poseidon; his features are gloomy, his hair falls over his forehead; his attributes are a sceptre and Cerberus; he carries the key of the world below (cf. the epithet παλατρης, "keeper of the gate"), and is frequently in company with Persephone. He is sometimes represented as an agricultural god, carrying a cornu copiae and a two-pronged fork. Amongst the Romans Hades was usually called Dis pater (the "wealthy father") and Orcus, although the name Pluto is often used. Orcus, however, was rather the actual slayer, the angel of death, while Father Dis was the ruler of the dead. The Etruscan god of death was represented as a savage man with wings and a hammer; at the gladiatorial games of Rome a man masked after this fashion removed the corpses from the arena. In Romanesque folk-lore Orcus (possibly English "ogre," q.v.) has passed into a forest-elf, a black, hairy, man-eating monster, upon whose house children lost in the woods are apt to stumble, and who sometimes shows himself kindly and helpful.

The "house of Hades" was a dreadful abode deep down in the earth, and the god was invoked by rattling on the ground. According
to another view, the realm of Hades was beyond the ocean in the far west, which to the Greek was always the region of darkness and death, as the east of light and life. This is the view of Hades popularized in the Odyssey. Heroes and taken the golden fish to another passage of the Odyssey (iv. 561 seq.) a picture of Elysium, a happy land at the ends of the earth, where rain and snow fall not, but the cool west wind blows and men live at ease. After Hades had welcomed the heroes and taken the golden fish, we find in

PLUTOCRACY—PLYMOUTH

PLYMOUTH, a municipal county (1888, extended 1896) and parliamentary borough and seaport of Devonshire, England, 231 m. W.S.W. of London. Pop. (1910), 126,266. It lies at the head of Plymouth Sound, stretching westward from the river Plym towards the mouth of the Tamar, from which it is separated by the township of East Stonehouse and the borough of Devonport, the two later constituting with it the "Three Towns." The prince of Wales is lord high steward of the borough, which is divided into 24 wards, under a mayor, 14 aldermen and 44 councillors. The parliamentary borough, returning two members, is not coextensive with the municipal borough, part of the latter being in the Tavistock (county) division of Devon. The water frontage of the Three Towns consists of Plymouth Sound, with its inlets, in order from east to west, the Catwater, Sutton Pool, Mill Bay, Stonehouse Pool and the Hamoaze. The Catwater and Hamoaze are flanked on the east and west respectively by high ground, on which are built forts that command the harbour and its approaches. On the western side of the entrance to Catwater is the Citadel, founded in the reign of Henry VIII. and rebuilt by Charles II. The adjacent Hoe extends along the northern edge of the Sound, and from it can be obtained a splendid view, embracing the rugged Staddon Heights on the east and the wooded slopes of Mount Edgcumbe on the west. To the north is seen the town of Plymouth rising up to the hills known as Mannamed. On the site of an old Trinity House obelisk landmark is Smeaton's lighthouse tower, removed from its original position on the Eddystone Reef in 1884. It is now used as a wind-recording station in connexion with the adjoining Meteorological Observatory. On the Hoe there stands the striking Drake statue by Sir Edgar Boehm, and the Armada Memorial, while at the north-east end is an obelisk monument to the memory of troops engaged in the South African War. A municipal bowling-green recalls a probable early use of the Hoe. Adjacent to the Citadel, at its south-west angle, is the Marine Biological Station, and, further west, projects the Promenade Pier. In the Sound is Drake's (formerly St Nicholas') Island, now strongly fortified, at one time the property of the corporation, and serving in Stuart times as a place of imprisonment of certain Plymouth Baptist ministers. Few evidences, however, of the antiquity of the town remain. Below, and to the north-east of the Citadel, is the Barbican with its " Mayflower " commemoration stone, a large fish-buying trade being done on the adjacent quay, near which is the Custom House. From the Barbican winding streets lead past the old Guildhall (1500) which contained the municipal library, its more recent quarters in the new museum, opposite the technical and art schools, situated in the most northern part of the town. At a short distance west stands the new Guildhall, with the enlarged post office, central police station, law courts and municipal buildings in close proximity. Opened in 1874, the Guildhall is built in a bold, rather exotic, Early Pointed French style. The tower at the south-west end is 150 ft. high, and the building is ornamented with a series of coloured windows relating to events in the history of Plymouth or commemorating men and families connected with the town. The large hall contains a fine organ. In the mayor's parlour is a contemporary picture of Sir Francis Drake and some interesting points of the town of Plymouth.

Near the eastern entrance to Guildhall Square is St Andrews, the mother church of Plymouth, erected on the site of a chapel dedicated to the Virgin. The church is typical of the Devonshire Perpendicular style of 1480-1520, but, though large, presents few features of artistic or archaeological interest. It underwent complete restoration in 1874. The burying-ground on the north side has been levelled, and on it erected a stone monument. The church, furnished with one of the finest organs in the west of England, contains the tombs of a son of Admiral Vernon, of Sir John Skelton (a former garrison of the Citadel), and of Captain Nathaniel on the Devonport, as well as monuments of the bodies of Probationer Drake and Here Katherine of Aragon returned thanks for a safe voyage from Spain to Plymouth. In 1642 a second parish was formed with Charles
PLYMOUTH

Church (1658) at its head, the last-named being popularly known as New Church, in contradistinction to St Andrews or “Old Church.” The New Church is an interesting specimen of Stuart “debased” Gothic architecture. South of Andrews church is the site of a Franciscan Friary with some early 15th-century remains. Near the church are a few old houses scattered along the crooked little streets going down to the water. These houses date from Elizabethan times, but are not of any unusual interest. The Citadel (now used as army headquarters and barracks) is a fine specimen of 17th-century military architecture. It is an irregular bastioned pentagon in trace. It possesses a fine florid classical gateway. In the centre stands a dignified Jacobean house, once the residence of the governor of Plymouth.

Plymouth is the seat of a Roman Catholic bishopric founded in 1851, the cathedral, in Wyndham Street, being completed in 1858 through the efforts of Bishop Vaughan, who was the second occupant of the see (until 1902). The building is in the Early English style, and adjoining are the bishop’s house and the convent of Notre Dame. In the immediate vicinity is the only Presbyterian church in the Three Towns. Noteworthy among the many Nonconformist places of worship are the Baptist chapel (George Street), with its tablet recording the imprisonment of ministers on Drake’s Island; Sherwell (Congregational) on the Tavistock Road, the most ornate in its style of architecture; the Wesleyan Methodist chapel in the main thoroughfare of the residential suburb of Mutley, unique among Methodist edifices in the town in respect of its fine spire. All the principal religious bodies have places for worship or for assembly in the town, and the borough has given, in popular speech, the name of “Plymouth Brethren” to one body.

In addition to the Plymouth College (for boys), there are several educational institutions administered by the borough council, comprising a science, art and technical school, a mixed secondary school replacing the corporation grammar school of Elizabethan foundation, and intermediate day and evening school and numerous primary departments. The philanthropic institutions include the enlarged South Devon and East Cornwall hospitals, eye infirmary, homoeopathic hospital, blind institution and female orphan asylum.

The public recreation grounds, other than the Hoe, are few and small; Hartley Reservoir Grounds at the northern extremity of the town commands extensive moorland views; the Freedom Park, by its plain, unfinished monument, recalls the siege of Plymouth by the Royalists in 1646, and the Beaumont Park contains the temporary home of the nucleus for a museum and art gallery. The Victoria Park, redeemed from a part of Stonehouse Creek, is under the joint administration of Plymouth, Stonehouse and Devonport.

The township of East Stonehouse, having Plymouth on the east, is separated from Devonport on the west by the Stonehouse Pool Creek, which is crossed by a toll-bridge and thoroughfare known locally as the “Half-penny Gate Bridge.” A manor of the Mount Edgcumbe family, East Stonehouse, is an urban district, in the administrative county of Devon, with a council of 15 members, but is unitied for parliamentary purposes with Devonport, with which it returns two members. Within the boundaries of Stonehouse are the Royal Naval Hospital (1762), the Royal Marine Barracks (1705) in Durnford Street, and the Royal William Victualling Yard (1825), the last-named having frontage on the Hamoaze, which separates the Devon from the Cornish portion of the Stonehouse manor.

The Stanehus(e) of Domesday Book ultimately passed into the hands of the Vallerots, whose hamlet of West Stonehouse stood on the Cornish side of the Tamar, for (to quote Carew’s Sarrey) “certain old ruins yet remaining confirm the neighbours’ report that near the water’s side, there stood once a towne called West stonehouse until the French (1557?) by fire and sword overthrew it.”

St George’s (1758) is the oldest of the three parishes of Stonehouse, and on the site of the present church stood the chapel of St George, in which, during the years 1681-1682, worshipped, in addition to the English congregation, one composed, as at Plymouth, of Huguenots who fled from France at the Revocation of the Edict of Nantes.

Facing the Sound are Stone Hall and the Winter Villa. The former, occupied by the lords of the manor before the building of Mount Edgcumbe House, was originally a castellated building, and the latter was built primarily as an alternative residence for a countess of Mount Edgcumbe. A link with the past is the Mill Bridge Causeway, over what was the “Dead Lake,” now a road, which, at the head of Stonehouse Creek, is the second approach to the Stoke Damerel portion of Devonport. Built in 1525, it possesses a toll-gate house at which payment from vehicles is still demanded.

In addition to the Victualling Yard, with its naval ordnance department, repairing shops and armoury, the Barracks, accommodating some 1500 men, and the Naval Hospital of 24 acres, abutting on the Creek, there are within the boundaries a building seating over 2000 persons, the Devonport Corporation Electricity Works, a clothing factory and part of the Great Western Railway Docks. The stationary character of the township—which from its situation is incapable of expansion—is seen from the statistics of population: (1881), 15,041; (1901), 15,108; (1910), 15,111.

The “Port of Plymouth” in 1311 embraced Plympton, Modbury and Newton Ferrers, and received a customs grant
from Richard II. In 1435 sixty-five cargoes were imported, and in the reign of Elizabeth it rose to be the foremost port in England. The 18th century saw a great development of trade with Virginia and the West Indies, resulting in the establishment of a sugar-refining industry that was maintained until a recent date.

In 1749 the "town's water" was carried to the Barbican to supply shipping. The port of Plymouth, as at present constituted, embraces the waters of Plymouth Sound and the Hamoaze, including all bays, creeks, lakes, pools, ponds and rivers as far as the tide flows within or to the northward of a straight line drawn across the entrance of Plymouth Sound from Pennel Point on the west to the Shagstone on the east. The chief water area within the limits of the port is the Sound with its inlets, the Catwater (200 acres), Sutton Pool, Mill Bay, Stonehouse Pool and the Hamoaze. The Sound itself covers an area of 4500 acres and is sheltered from south-west gales by the breakwater completed in 1841 at a cost of 1½ million sterling. It lies 2½ m. south of the Hoe, and is nearly a mile long, 360 ft. wide at the base and 45 ft. at the top. Its cant bends inwards at angles of 120°; at the western end is a lighthouse and at the eastern extremity is a pyramidal beacon with a cage capable of accommodating several men.

Plymouth, the Seat of Domesday, was afterwards divided into the town of Sutton Prior, the hamlet of Sutton Vallercott and the tithing of Sutton Ralph, the greater part belonging to the priory of Plympton. The market, established about 1253, became in 1311 town property, with the mayor as clerk of the market. In 1292 the town first returned members to parliament. In the 14th century it was frequently the port of embarkation and of disembarkation in connexion with expeditions to France, and suffered considerably at the hands of the French. In 1412 the inhabitants petitioned for a charter, which, after several oppositions from the priors of Exeter, was granted by Henry VI. in 1430. In the discovery of the New World it played a part of great importance. Cockeram, a native of the town, sailed with John Cabot in 1497. Sir John Hawkins and his father William were also natives, the former being post admiral and (in 1571) M.P. From Plymouth in 1577 Drake set out on his voyage round the world; in 1581 he became mayor and represented the borough in parliament during 1592-1593. Sir Humphrey Gilbert (M.P. 1571) sailed on his second colonizing expedition to America in 1583 from the port, and hither Drake brought the remnant of Raleigh's Virginian colony. Plymouth supplied seven ships against the Armada, and it was in this port that the English fleet awaited the approach of the Spaniards. A stone on a quay at the Barbican records the fact that this was the last port touched by the Pilgrim Fathers on their voyage to America.

During the Civil War Plymouth was closely invested by the Royalists, whose great defeat is commemorated by the monument at Freedom Park. It was the only town in the west that never fell into their hands. It early declared for William of Orange, in whose reign the neighbouring dockyard was begun.

Proc.). (H. G. de W.)
for binding wheat is one of the principal products. From 1900 to 1905 the capital invested in manufactures increased 83% and the value of the product 104%. Large quantities of cranberries are raised in the township. Plymouth is a port of entry, but its foreign commerce is unimportant; it has a considerable coasting trade, especially in coal and lumber. The town ship owns its waterworks.

Plymouth was the first permanent white settlement in New England, and dates its founding from the landing here from the "Mayflower" sloop of an exploring party of twelve Pilgrims, including William Bradford, on the 21st of December (6.) in 1620. The name of the place was afterwards put by the colonists called it New Plymouth, because they had sailed from Plymouth, England, and possibly because they were aware that the name of Plymouth had been given to the place six years before by Captain John Smith. When and how the town and the colony of Plymouth became differentiated is not clear. Plymouth was never incorporated as a township, but in 1633 the General Court of the colony recognized it as such by ordering that "the chief government be yeowed to the town of Plymouth." In 1666 the colony submitted to Sir Edmund Andros, who had been commissioned governor of all New England, and chose representatives to sit in his council. Plymouth remained the seat of government of the colony of New England, or Colony, and with it the town of Plymouth, was united to Massachusetts Bay under the charter of 1691 (see Massachusetts: History). Part of Plymouth was established as Plympton in 1707, and part as Kingston in 1726.

Channing and W. W. Channing; the article by Herbert B. Adams in the Magazine of American History, July, 1881, and that by S. H. Gay in the Atlantic Monthly, xlvii. 612 sqq.

PLYMOUTH, a borough of Luzerne county, Pennsylvania, U.S.A., on the north branch of the Susquehanna river, immediately west of and across the river from Wilkes-Barre, of which it is a suburb. Pop. (1910), 16,996. Plymouth is served by the Delaware, Lackawanna & Western railroad. The borough is finely situated in the Wyoming Valley among the rich anthracite coalfields of eastern Pennsylvania, and its inhabitants are chiefly engaged in the coal industry; in 1906 and 1907 (when it shipped 24,081,401 tons) Luzerne county shipped more anthracite coal than any other county in Pennsylvania. In 1906 the total value of the factory products was $900,778, 85.4% more than in 1900. Before the coming of the white settlers there was an Indian village called Shawnee on the site of the present borough. The township of Plymouth was settled in 1769 by immigrants from New England—many originally from Plymouth, Litchfield county, Connecticut, whence the name—under the auspices of the Susquehanna Company, which claimed this region as a part of Connecticut, and Plymouth became a centre of the contest between the "Pennamites" and the "Yankees" (representing respectively Pennsylvania and Connecticut), which grew out of the conflict of the royal charter of Pennsylvania (granted in 1687) with the royal charter of Connecticut (granted in 1662), a matter which was not settled until 1799. (See Wyoming Valley.) In its earlier history the region was agricultural. Two brothers, Abijah and John Smith, originally of Derby, Conn., settled in Plymouth in 1800 and began shipping coal thence in 1808; this was the beginning of the anthracite coal trade in the United States. The borough was incorporated in 1866, being then separated from the township of Plymouth, which had a population in 1890 of 8,963 and in 1900 of 9,653.

See H. B. Wright's Historical Sketches of Plymouth (Philadelphia, 1878).  

PLYMOUTH BRETHREN, a community of Christians who received the name in 1830 when the Rev. J. N. Darby induced many of the inhabitants of Plymouth, England, to associate themselves with him for the promulgation of his opinions. Although small Christian communities existed in Ireland and elsewhere calling themselves Brethren, and holding similar views, the accession to the ranks of Darby so increased their numbers and influence that he is usually reckoned the founder of Plymouthism. Darby (born in Nov. 1800 in London; graduated at Trinity College, Dublin, in 1816; died April 29, 1882, at Bournemouth) was a curate in Wicklow 1825-1827, when he felt himself constrained to leave the Anglican communion; going to Dublin, he became associated with several devout people who met stately for public worship, and called themselves "Brethren." Among these were A. N. Groves and J. G. Bellett, who deserve to rank among the founders of the movement. In 1830 Darby at Plymouth won over many people to his way of thinking, among them James L. Harris, a Plymouth clergyman, and the well-known Biblical scholar Samuel Prideaux Tregelles. The Brethren started a periodical, The Christian Witness, continued from 1849 as The Present Testimony, with Harris as editor and Darby as the most important contributor. During the next eight years the progress of the sect was rapid, and communities were founded in many of the principal towns in England.

In 1856 Darby went to reside in France, Switzerland, and made many discipled. Congregations were formed in Geneva, at Lausanne, where most of the Methodist and other dissenters joined the Brethren, at Vevey and elsewhere in Vaud. His opinions also found their way into France, Germany, German Switzerland, and Italy; but French Switzerland has always remained the stronghold of Plymouthism on the Continent, and for his followers there Darby wrote two of his most important tracts, Le Ministre considéré dans sa nature et De la Présence et de la Passion of the Spirit in the Church. The revolution in the canton Vaud, brought about by Jesuit intrigue in 1845, brought persecution to the Brethren in the canton and in other parts of French Switzerland, and Darby's life was in great jeopardy.

He returned to England, and his reappearance was followed by divisions among the Brethren at home. These divisions began at Plymouth. Benjamin Wills Newton, head of the community there, who had been a fellow of Exeter College, Oxford, was accused of departing from the testimony of the Brethren by reintroducing the spirit of clericalism. Unable to detach the congregation from the teacher, Darby began a rival assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority remained with Newton. The separation became wider in 1847 on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesa congregation at Bristol, where George Müller was the most influential member, received into communion several of Newton's followers and justified their action. Out of this came the separation into Neutral Brethren, led by Müller, and Exclusive Brethren or Darbyites, who refused to hold communion with the followers of Newton or Müller. The Exclusive, who were the more numerous, suffered further divisions. An Irish clergyman named Samuel O'Malley Cluff had adopted views similar to those of Pearsall Smith, who preached a doctrine of sanctification called "Death to Nature" as an antidote to the supposed prevalent Laodiceanism, and when these were repudiated seceded with his followers. The most
important division among the Exclusives came to a crisis in 1881, when William Kelly and Darby became the recognized leaders of two sections who separated on a point of discipline. This was followed (1885) by the disruption of the strict Darbyite sect, two communions being formed out of it upon points of doctrine.

There were thus six sections of Plymouthists: (1) the followers of B. W. Newton, who promulgated the prophetic views peculiar to their leader; (2) the Neutrals—open brethren, leaning to Baptist views and to the Congregationalist idea that each assembly should judge for itself in matters of discipline, headed by George Müller; (3) the Exclusives, the Darbyites, holding what may be described as a Pauline view of the Church, who claim to be the original Brethren, represented by J. B. Stoney and C. H. Mackintosh; (4) the Exclusives associated in Great Britain with C. E. Stuart, in America with F. W. Grant; (5) the Exclusives who followed W. Kelly, giving a general adhesion to Darby but with a tendency to place conscience above church action, holding the Pauline view of the Church modified by Johannine elements; and (6) the Exclusives who followed Cluff. The fundamental principle of the Exclusives, "Separation from evil God's principle of unity," has led to many unimportant excommunications and separations besides those mentioned.

The theological views of the Brethren differ considerably from those of their rivals. In the American list of dissenting sects, see Teulon, History and Doctrines of the Plymouth Brethren), the make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. Those who have opposed or sneered at Presbyterians or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and sets aside the Holy Spirit's guidance. The gradual growth of this opinion, and perhaps the reason, for the separations, is that an earlier era of watching. While a curate in Ireland he was indignant with Archbishop Magee, who had stopped the progress of mission work among Roman Catholics by imposing on all who joined the church the oath of subscription, as a barrier to the free establishment of all as foreign to the spirit of Christianity as the papacy is ("Considerations addressed to the Archbishop of Dublin," &c., Coll. Work, 1, 1). The pamphlet has been much reprinted, and has been received as a warrant for prohibiting the preaching of the gospel within a parish where the incumbent was opposed to it, led him to consider the whole system a hindrance to the proper work of the church and therefore anti-Christian ("Thoughts on the present position of the Home Mission," Coll. Workts, i. 78). And the waste of public implied in the refusal to sanction lay preaching seemed to him to lead to the conclusion that an official ministry was a refusal of the gifts of the Spirit to the church ("The Brethren, or Lay Preaching," Coll. Workts, p. 200). The movement, if it has had small results in the formation of a sect, has at least set churches to consider how they might make their ministry more elastic. Perhaps one of the reasons of the comparison was built by the Brethren to show that their mission is not to the heathen but to the "awakened in the churches.

The movement has a distinct interest for students of church history: (1) as illustrating again the desire of certain Christians to pass over the garnered experience of the centuries, and by going straight to the Bible to make a fresh start without any other authority, precedent or guidance; (2) in its development along the Evangelical, Tractarian and Broad Church movements of the 19th century and its affinities with them. All a certain haphazardness that has always marked the Brethren is responsible for the present lack of unity. The early movement has waned, and no provision was made for proper theological study.

PLYMPTON ST MARY and PLYMPTON MAURICE (or EAR'S), two small adjacent towns in the southern parliamentary division of Devonshire, England, 5 m. N.E.E. of Plymouth, on the Great Western railway. Pop. (1901), Plympton St Mary, 3587; Plympton Maurice, 1139. Plympton St Mary contains a fine Decorated and Perpendicular church, with a lofty tower of the later period. Near it are remains of the former rich Augustinian priory of Plympton, founded by William Wearleston, bishop of Exeter (1107-1156). They include an Early English refectory with Norman undercroft, the kitchen and other fragments; but there are no remains of the great priory church. At Plympton Maurice are slight ruins of the castle built by Richard de Redvers, 1st earl of Devon (whence the variant of the name), in the time of Henry I. There are several picturesque old houses in the town, together with a guildhall built 1606, and a grammar school founded in 1658, of which Sir Joshua Reynolds's father was master.

Plympton (Plinlona) bears traces of very ancient settlement, the earthworks on which in the 12th century Richard de Redvers reared his Norman castle being probably of British origin, while a Saxon document dated 904 records a grant by Edward the Elder to Asser, bishop of Sherborne, of twelve manors in exchange for the monastery of "Plymton." According to the Domesday survey "Plinlona" was a royal manor assessed at £23, and the fact that the canons at Plympton held two hides apart from these shows the origin of the later division into the priory parish of Plympton St Mary and the secular borough of Plympton Erle. In the 12th century Plympton appears as a mesne borough under the lordship of the Redvers, earls of Devon, and in 1224 the burgesses claimed to have received a charter from William, the 6th earl, of which however nothing further is known, and the first charter of which a copy is extant was issued by Baldwin de Redvers in 1242, granting to the burgesses of Plympton the borough, with fairs and markets, and the liberties enjoyed by the citizens of Exeter, in consideration of a yearly payment of £24, 2s. 2d. In 1437 a charter from Edward, 4th earl, granted to the burgesses an eight-days' fair at the Feast of the Nativity of St. John the Baptist, but at this period the growing importance of Plymouth was steadily robbing Plympton of its position as head of the district. In 1602, in response to a petition of the burgesses, Elizabeth issued a charter of incorporation, instituting a common council to consist of a mayor and 8 principal burgesses; a Saturday market, and fairs at the Feasts of the Ascension and the Annunciation. A code of by-laws dated 1623 mentions a fair on St Luke's Day in addition to the three above mentioned. The borough surrendering its charter to Charles II. in 1684, and in 1685 received a fresh charter from James II. instituting an additional market on Wednesday and a fair on the 1st of August. This charter was declared invalid in 1690, but its provisions were reaffirmed in 1692, with the addition of an eight-days' fair to begin on the 14th of February. The borough, which had returned two members to parliament since 1205, was disfranchised by the Reform Act of 1832 and from this date the municipal privileges gradually lapsed, and in 1859 were finally abolished.

See Victoria County History: Devonshire; William Cotton, Some Account of the Ancient Borough Town of Plympton St Mary (London, 1890); J. Brooking Rowe, Notes of Plympton Castle (Plymouth, 1880).

PNEUMATIC DESPATCH, the name given to a system of transport of written despatches through long narrow tubes by the agency of air pressure. It was introduced in 1853 by J. Latimer Clark, between the Central and Stock Exchange stations of the Electric and International Telegraph Company in London. The stations were connected by a tube 13 in. in diameter and 220 yds. long. Carriers containing batches of telegrams, and fitting piston-wise in the tube, were sucked through it (in one direction only) by the production of a partial vacuum at one end. In 1858 C. F. Varley improved the system by using compressed air to force the carriers in one direction, a partial vacuum being still used to draw them in the other direction. This improvement enabled single radiating lines of pipe to be used both for sending and for receiving telegrams between a central station supplied with pumping machinery and outlying stations not so supplied.

Radial System.—In the hands of R. S. Culley and R. Sabine the radial system of pneumatic despatch was in 1870 brought to great perfection in connexion with the telegraphic department of the British post office, since that date the total length of tubes (which are employed for telegrams only) has been very largely increased (in 1909 there was in London a total length of 5

The

"D" box—so named

from the shape of its cross section. This box is of

cast iron, and is provided with a close-fitting,

brass-framed, sliding lid with a glass panel. This

lid fits air-tight, and closes the box after a carrier has

been inserted into the mouth of the tube; the latter enters at

one end of the tube (in one of the above methods). A supply

pipe to, which is connected a " 2-way" cock, is joined to

the box and allows communication at will with either the

"pressure" or "vacuum" mains, so that the apparatus becomes

available for either sending (by pressure) or receiving (by vacuum)

a carrier. Automatic working, by which the air supply is

automatically turned on on the introduction of the carrier into a

tube and on closing of the D box, and is cut off when the

carrier arrives, was introduced in 1900.

On the long tubes (over about 1000 yds.) a modification of the

"D" box in its simplest form is necessary; this modification

consists in the addition of a "sluice" valve placed at a distance

of about 9 in. (i.e. rather more than the length of a carrier)

from the mouth of the tube. The sluice valve, by means of an

interlocking arrangement, is so connected with the sliding lid

of the box that the lid cannot be moved to the open position

unless the sluice valve has closed the tube, nor can the sluice

valve be opened unless the sliding lid is closed. The object

of this sluice valve is to prevent the back rush of air which would

take place into the tube when the sliding lid is opened to take

out a carrier immediately on the arrival of the latter; for although

the vacuum may be turned off by the 3-way cock, yet, owing
to the great length of the tube, equilibrium does not immediately

take place in the latter, and the back rush of air into the vacuum

when the lid is opened to extract the carrier will cause the latter

to be driven back down the tube. The sluice also prevents a

similar, but reverse, action from taking place when pressure

working is being carried on.

As a rule, only one carrier is despatched at a time, and no

second carrier is inserted in the tube until the arrival of the

first one at the farther end is automatically signalled (by an

electric apparatus) to the despatching office. On some of the

long tubes a carrier, when it passes the midway point in the tube,

strikes a trigger and sends back an electrical signal indicating

its passage; on the receipt of this signal a second carrier may

be despatched. This arrangement has been almost entirely

superseded by a signalling apparatus which by a clock movement

automatically indicates how far the carrier has passed and moves the latter to "tube closed"

certain definite time (30 to 40 seconds) after a carrier has been

inserted in the tube. By this arrangement carriers can be

despatched one after the other at comparitively short intervals of
time, so that several carriers (separated by distinct intervals)

may be travelling through the tube simultaneously. It is

necessary that the carriers be separated by a definite interval,

otherwise they tend to overtake one another and become jammed

The horse-power required to propel a carrier is approximately,

for pressure:—

\[
H.P. = \left(\frac{P_{1}v}{I}\right)^{1/2} \quad \text{for vacuum:—}
\]

\[
H.P. = \left(\frac{5187 - 1 - 234\sqrt{15}}{P_{1}v}\right)^{1/2} \quad \text{for vacuum:—}
\]

For a given transit time the actual horse-power required is much

less than the case of vacuum, in the case of pressure working,

owing to the density of the air column moved being much less:

thus, for example, the transit time for 10 lb pressure is the same

as for 6 lb vacuum, but the horse-power required in the two cases

is about 2:10. A carrier made to work at 10 lb per square inch

pressure, will have a transit time of 21 minutes, and will theoretically require 3.5 horse-power to be

expended in working it, although actually 25-20% more horse-power than the case of vacuum

must be allowed for, owing to losses through various causes. The transit time for a 21-in. tube is 16% more than for

a 3-in. tube of the same length, when both are worked at the same

pressure, but the horse-power required is 50% less; it is not ad-

visable, therefore, to use a tube larger than is absolutely necessary to carry the volume of traffic required.

The somewhat complicated pattern of "double sluice valve"

originally used at the central stations has been superseded by a

simpler form, known as the "D" box—so named from

The tubes are in all cases of lead, the 24-in.

are enclosed in the 3-in.

cast-iron pipes made in lengths of 9 ft.

Great care is exercised in making the joints in the lead pipes.

Before the tube is placed in its trench a strong chain is passed

through it, and a polished steel mandrel, 6 in. long and slightly

less in diameter than the diameter of the tube, is heated and

attached to the chain, and pushed half its length into the end of

the tube already laid; the new length of tube is then forced over

the projecting end of the mandrel until the tube ends (which have

been previously cut flat) butt perfectly together; an ordinary

plumber's joint is then made. By this means the tube is made

perfectly air-tight, and the mandrel keeps the surface of the tube

under the joint as smooth as at any other part of its length. After

the joint is completed the mandrel is drawn out by the chain

attached to it, the next length is drawn on, and the above process

repeated. The tubes are laid about 2 ft. below the surface of the

ground.

The tubes radiate from the central to the branch offices,

the principal offices having two tubes, one for "inward" and

the other for "outward" traffic. At the smaller

offices both the inward and the outward traffic is

carried on through one tube. The "carriers" are made with gutta-

percha bodies, covered with felt, the front of the carrier being

provided with a buffer or piston formed of several disks of felt

which closely fit the tube; the messages are prevented from get-
in out of the carrier by the end being closed by an elastic band,

which can be stretched sufficiently to allow the message forms to be

inserted. The 3-in. carriers will hold 75 ordinary message

forms, the 24-in. carriers 25 forms, and the 15-in. carriers

20 forms. The carriers are propelled in one direction (from the

central office) by "pressure," and drawn in the opposite direction

by "vacuum," the standard pressure and vacuum being 10 lb

and 45 lb per sq. in. respectively, which values give approxi-
nately the same speed.

The time of transit of a carrier through a tube when the air

pressure does not exceed 20 lb per square inch is given very

approximately by the empirical formula:

\[
t = \frac{0.0872}{P_{1}} \sqrt{\frac{d}{I}}
\]

where \(I\) = length of tube in yards, \(d\) = diameter of tube in inches, 
\(P_{1}\) = effective air-pressure in pounds per square inch, \(t\) = transit

time in seconds. For vacuum the formula is:

\[
t = \frac{0.0825}{P_{1}} \sqrt{\frac{d}{I}}
\]

where \(P_{1}\) = effective vacuum in pounds per square inch.
in the tube. Although the stoppage of a carrier in a tube is of exceedingly rare occurrence, it does occasionally take place, through picks being driven into the tube by workmen executing repairs to gas or water pipes, but the locality of such a stoppage is easily determined by a simple inspection along the route of the tube. In no case is any special means of testing for the locality from the telephone found necessary.

Circuit System.—Another method of working, extensively used in Paris and other continental cities, is the circuit system, in which stations are grouped on circular or loop lines, round which carriers travel in one direction only. In one form of circuit system—that of Messrs Siemens—a continuos current of air is kept up in the tube, and rocking switches are provided by which carriers can be quickly introduced or removed at any one of the stations on the line without interfering with the movement of other carriers in other parts of the circuit. More usually, however, the circuit system is worked by despatching carriers, or trains of carriers, at relatively long intervals, the pressure or vacuum which gives motive power being applied only while such trains are on the line. On long circuits means are provided at several stations for putting on pressure or vacuum, so that the action may be limited to that section of the line on which the carriers are travelling at any time. In America, in New York, Boston and Philadelphia, tubes (Batcheller system) up to 8 in. in diameter are in use. The tubes are of cast iron made in 12-ft. lengths and are carefully bored; they resemble ordinary water pipe. Short bends are made in seamless brass tube carefully bent to a uniform radius of twelve times the diameter of the tube, the tube being slightly larger in diameter than the main tube. The sending apparatus, or transmitter, is similar to the Siemens switch before described, and consists of two sections of the tube supported in a swinging frame so arranged that either section can be brought into line with the main tube, in which a current of air is constantly flowing. One of these tube sections maintains the continuity of the main tube, while the other is swung to one side to receive a carrier. In despatching, a carrier is placed in an iron trough and then pushed into the open tube section. The frame carrying the two tube sections is then swung until the section containing the carrier is brought into line with the main tube, when the carrier is swept along with the current of air. When the frame is swinging from one position to another the air is prevented from escaping by plates that cover the ends of the tube, and a by-pass is provided so that the current is not interrupted. An air motor, consisting of a cylinder and piston, furnishes the power to swing the frame, the operation requiring an instant only. When the controlling lever is pulled and latched the frame swings, and as the carrier passes out of the apparatus it trips the lever, and the frame swings back automatically into position to receive another carrier. To prevent carriers from being despatched too frequently and overtaking each other a time lock is attached to the sending apparatus; this locks the controlling valve when a carrier is despatched, and keeps it locked for a given period of time, varying from five to fifteen or twenty seconds, according to the adjustment of the lock. The carrier is received at the farther end of the tube into an air cushion formed by closing the end of the tube with a sluice-gate, and allowing the central force of the train to flush out the branch pipe through slots in the tube located about 4 ft. in the rear of the sluice-gate. When a carrier arrives it passes over the slots, enter the air cushion and is brought to rest without injury or shock. The carriers are thin steel cylinders closed at the front end by a convex disk of the same material carrying a buffer of felt and leather; the rear end is closed by a hinged lid secured by a lock. The shell of the carrier is 24 in. long and 7 in. in diameter for the 8-in. tube; it is secured by two bearing-rings of woven cotton fabric clasped between metal rings; the rings are renewed after about 2000 m. of travel. The tubes are worked at a pressure of 6 lb per sq. in., and for a distance of 4300 ft. require about 30 horse-power, the transit speed being 30 m. per hour.

In addition to its use for postal and telegraphic purposes the pneumatic despatch is employed for internal communication in offices, hotels, &c., and also in shops for the transport of money and bills between the cashier's desk and the counters.

References.—The system used in the United Kingdom is fully described in a paper by Messrs Culley and Sabine (Min. Proc. Inst. Civ. Eng. vol. xliii.). The same volume contains a description of the pneumatic telegraphs of Paris and of experiments on them by M. Bontemps, and also a discussion of the theory of pneumatic transmission by Professor W. C. Unwin. Reference should also be made to a paper, by C. Siemens (Min. Proc. Inst. Civ. Eng. vol. xxiii.), describing the Siemens circuit system; and to Les Télé-\n

PNEUMATIC GUN.

Air as a propellant has in recent years been applied to guns of large calibre, in which its comparatively gentle action has proved advantageous when high explosives contained in their shells are employed as projectiles. In 1883 Mr Mefford of Ohio utilized an air pressure of 500 lb per sq. in. in a 2-in. gun, and succeeded in propelling a projectile 2100 yds. The arrangement was of the simplest form—a hose with an ordinary cock by which the air was admitted into the gun behind the projectile. The question was then taken up by Capt. E. L. Zalinski (1849-1900) of the United States Artillery, who in 1888 reduced the so-called "dynamite gun" to a practical shape and obtained excellent firing results.

The principal features of his system are: (1) An extremely ingenious balanced valve admitting the air pressure into the gun. This valve is opened and closed by a simple movement of the firing lever, and is capable of adjustment so that the propelling force, and consequently the range, can be regulated. (2) A light steel projectile carrying the bursting charge, and provided with a tail to which vanes are attached in order to give rotation. (3) Electric fuses of entirely original design. Each shell carries a wet battery, the current from which fires the charge on impact with any solid object, and a dry battery which becomes active after the shell has dived below the surface of the water, and ignites the charge after the shell is underway. For safety all the electric circuits are made to pass through a disconnector, which prevents them from being completed until the shell has been fired. The gun is a built-up smooth-bore tube, 15 in. or less in diameter. The full-calibre shell weighs 1000 lb, and carries a bursting charge of 600 lb of blasting gelatine, cut into the form of chevrons, fitting the steel envelope, and provided with a core of dry gun-cotton as a primer. Sub-calibre projectiles, 10 in. and 8 in., can be used in their case, rotation is given by vanes or fins attached to the body of the shell. Air at 1000 lb pressure is stored in tubes close to the gun, and is supplied from primary reservoirs, to which it is directly

Dynamite gun, mounted at Sandy Hook, New York Harbour.
PNEUMATICS—PNEUMATOLYSIS

pumped at a pressure of about 2000 lb. There is, therefore, a considerable reserve of power available without pumping. Flushing: by fatigue on the principal of the hammers has many zoolites for the protection of New York and San Francisco. With a full-calibre shell (1000 lb) these guns have a range of 2400 yds.; with a sub-calibre 8-in. shell (250 lb) the maximum range is 6000 yds. The off-hand gun is capable of replacing systems of many small guns with economy, and without the great objection of interfering with a waterway.

The only employment of the dynamite gun afloat has been in the case of the U.S. gunboat "Vesuvius," carrying three in the bows. These guns are fixed at a constant angle of elevation, and the range is regulated by the air valve, training being given by the helm. Thus mounted on an unstable platform, the accuracy of fire obtainable must evidently be much less than on shore. The "Vesuvius" was employed during the Spanish-American War of 1898, when on several nights in succession she approached the defences of Santiago under cover of darkness and discharged three projectiles. Fire delivered under such conditions could not be sufficiently accurate to injure coast defences; but the shells burst well, and made large craters. A small dynamite gun on a field-carriage was used in the land operations above Santiago in the same war.

PNEUMATICS (Gr. πνεύμα, wind, air), the branch of physical science concerned with the properties of gases and vapours (see Gas). A pneumatic trough is simply a basin containing water or some other liquid used for collecting gases.

PNEUMATOLYSIS (Gr. πνεύμα, vapour, and λύω, to set free), in meteorology, describes a change of vapour from fumaroles and the effects produced by them on rock masses. In all volcanic eruptions the gases given off by the molten lavas are powerful agencies. The slaggry clots of lava thrown out from the crater are so full of gas that when they cool they resemble spongy pieces of bread. The lava streams as they flow down the slopes of the volcano are covered with white steam clouds, while over the orifice of the crater hangs a canopy of vapour which is often darkened by fine particles of ash. Most authors ascribe volcanic explosions to the liberation of steam from the magma which held it in solution, and the enormous expansive powers which free water vapour possesses at very high temperatures.

Of these gases the principal are water and carbonic acid, but by analysis of the discharges from the smaller fumaroles, for the active crater is generally too hot to be approached during an eruption, it has been ascertained that hydrogen, nitrogen, hydrochloric acid, boron, fluorine, sulphuretted hydrogen and sulphuric acid are all emitted by volcanoes. A recent lava flow has been likened to a great fumarole pouring out volatile substances at every crack in its slagggy crust. Many minerals are deposited in these fissions, and among the substances produced in this way are ammonium chloride, ferric chloride and oxide, copper oxide (tenorite and cuprite) and sulphides. Hydrochloric acids on the surface of these rocks or on the air of the fumaroles or on the water of the cooling lava may react with the rocks and other secondary products are formed. These processes have been described as "juvenile" or "post eruptive," and it is believed that the amygdales which occupy the cavities of many porous lavas are not due really to weathering by surface waters percolating in from above, but to the action of the steam and other gases set free as the lava crystallizes. The zeolites are the principal group of minerals which originate in this way together with chlorite, chloralcod and calcite. The larger cavities (or geodes) are often lined with beautiful crystal groups of natrolite, sciolite, thomsonite, stilbite, and other minerals of the same order.

The active gases were evidently in solution in the magma as it rose to the surface. Some geologists believe it is of subterranean origin like the lava itself, and is an essential or original component of the magma. They point to the exist-
metals are found, but often a much larger quantity of minerals such as calcite, barite, fluor spar, quartz and tourmaline which serve as a matrix or gangue, and have been deposited by the same agencies, and often at the same time as the valuable minerals.

In their passage upwards and outwards through the rocks of the country rocks, these gases and liquids not only deposit minerals in the fissures along which they ascend, but also influence the surrounding rocks and alter them in many ways. The granite or other plutonic mafic minerals are deposited at this time. They are especially liable to their influence, and it is probably because it is a high temperature, not having yet completely cooled down. Around the tin-bearing veins in granite there is extensive replacement of felspar and biotite by epidote, tourmaline and white micas (the last-named often rich in lithia). In this way certain types of altered granite are produced, such as greisen (g.z.) and schorl rock (see SCHOE.) In the slates adjacent to the tin veins tourmalinization also goes on, converting them into quartz veins. In the deviations of the veins into clays, epidote is also a pneumatolytische process, and is often found along with tin veins or other types of mineral deposit; probably both fluorine and carbonic acid operated in this last case along with water. Equally common and important is the silicification of rocks near mineral veins which carry gold, copper, lead and other metals. Granites and felsites may be converted into hard cherty masses of silica. Limestones undergo this transformation very readily; at the same time they are regarded as rocks very favourable to the deposition of ores. Probably the greatest example in which they undergo silicification and other types of metasomatic replacement is the formation of the veins of the sulphides of zinc and copper. The original minerals of these veins are largely replaced by calcite, epidote, chlorite, sericite and kaolin. Around granites intrusive into serpentine and other rocks containing much magnesia, there is a development of "peperitisation" or the deposit of talc and sericite in place of the original minerals of the rock. Some of the apatite veins of Canada and Norway accompany basic rocks of the gabbro group, and it has been contended that the apatite (which contains phosphorus and chlorine) was laid down by vapours or solutions containing those gases, which may play a similar part in the basic rocks to that taken by fluorine and boron in the pneumatolytische veins around granites. The very process by which the gangue is replaced (g.z.), a lime alumina silicate containing chlorine, often is substituted for lime-felspar.

These extensive changes attending the formation of mineral veins, replacing the common felspar, are in many cases the masses pneumatolytische action has contributed to the formation of pegmatites (g.z.).

PNEUMONIA (Gr. πνεύμων, lung), a term used for inflammation of the lung substance. Formerly the disease was divided into three varieties: (1) Acute Croupous or lobar pneumonia; (2) Catarrhal or Broncho-pneumonia; (3) Interstitial or Chronic pneumonia.

1. Acute Croupous or Lobar Pneumonia (Pneumonic Fever) is now considered as an acute infective disease of the lung, characterized by fever and toxæmia, running a definite course and being the direct result of a specific organism. It is the microcosm lanceolatus (pneumococcus, or diplococcus pneumoniae) of Fränkel and Weichselbaum is present in a large number of cases in the bronchial secretions, in the affected lung and in the blood. This organism is also present in many other infective processes which may complicate or terminate lobar pneumonia, such as pericarditis, endocarditis, peritonitis and empyema. The bacillus pneumoniae of Friedländer is also present in a proportion of cases, but it is probably not the cause of true lobar pneumonia. Various other organisms may be associated with these, but they are to be regarded as in the nature of a secondary invasion. Lobar pneumonia may be considered as an acute endemic disease of temperate climates, change in climate, or change of temperature, having been described. It has a distinct seasonal incidence, being most frequent in the winter and spring. Oeler strongly supports the view that it is an infectious disease, quoting the outbreaks reported by W. L. Rodman of Frankfurt, Kentucky, where in a prison of 735 inhabitants there were 118 cases in one year; but direct contagion does not seem to be well proved, and it is undoubted that the pneumococcus is present in the faeces of numbers of healthy persons and seems to require a lowered power of resistance or other favouring condition for the production of an attack.

Lobar Pneumonia begins by the setting up of an acute inflammatory process in the alveoli. The changes which take place in the lung are chiefly three. (1) Congestion, or engorgement, the blood-vessels being distended and the lung more voluminous and heavier than normal. Bloud is dark red in colour. Its air cell contains air. (2) Red Hepatisation, so-called from its resemblance to liver tissue. In this stage there is poured into the air cells of the affected part an exudation consisting of amorphous fibrin together with epithelial cells and red and white blood corpuscles, the whole forming a viscid mass which occupies not only the cells but also the finer bronchi, and which speedily coagulates, causing the lung to become firmly consolidated. In this condition the cells are entirely emptied of air, their blood-vessels are pressed upon by the exudation, and the lung substance, rendered brittle, sinks in water. The appearance of a section of the lung in this stage has been likened to that of red granite. It is to the character of the exudate, consisting largely of coagulable fibrin, that the term croupous is due. (3) Grey Hepatisation. In this stage the lung still retains its liver-like consistency, but its colour is now grey, not unlike the appearance of grey granite. This is due to the change taking place in the exudation, which undergoes resolution by a process of fatty degeneration, pus formation, liquefaction and ultimately absorption—so that in a comparatively short period the air vesicles get rid of their morbid contents and resume their normal function. During resolution the changes in the exudate take place by a process of autolysis or peptization whereby the uncoagulated exudate is broken down and absorbed, with resolution taking place into the lymphatics and circulation. The absorbed exudate is mainly excreted by the kidneys, excess of nitrogen being found in the urine during this period. This is happily the termination of the majority of cases of lobar pneumonia. One of the most remarkable phenomena is the rapidity with which the lung tissue clears up, and its freedom from alteration or from infiltration into the connective tissue as frequently takes place after broncho-pneumonia. When resolution does not take place, death may occur from extension of the disease and subsequent toxæmia, from circulatory failure, from the formation of one or more abscesses or more rarely from gangrene of the lung or from the complication mentioned below. Chronic interstitial pneumonia is infrequent, following on the acute variety. The most frequent seat of pneumonia is the base or lower lobes, but occasionally the apices are the only parts affected. The right lung is the most often attacked. Pneumonia may extend to the entire lung or it may affect both lungs. The death rate of acute lobar pneumonia in the chief London hospitals is 20%. With an organism so prevalent as the pneumococcus it follows that alcoholism, diabetes and other general diseases and intoxications must render the body liable to an attack. Making are more commonly attacked through one or other of the respiratory organs, and seem to give a special liability to another. The incubation period of pneumonia is unknown; it is probably very short.

The symptoms are generally well marked from the beginning. The attack is usually ushered in by a rigor (or in children a convulsion), and the speedy development of the febrile condition, the temperature rising to a considerable degree—101° to 104° or more. The respiratory rate becomes quickened, and breathing is often laboured and labored. The respiration, which is rapid, shallow and difficult, the rate being usually accelerated to some two or three times its normal amount. The lips are livid, and the face has a dusky flush. Pain in the side is frequently experienced. There should any amount of pleurisy be present, as is often the case. Cough is an early symptom. It is at first frequent and hacking, and is accompanied with a little tough colourless sputum, which, if very copious, and of a rusty red colour, either tenacious or frothy and liquid. Microscopically this consists mainly of epithelium, casts of the air cells and fine bronchi, together with granular matter, blood and pus. The condition of the lungs at this stage is not always so clear. Present are the pneumococcus, Friedländer's bacillus, and sometimes the influenza bacillus. The following are the chief physical signs in the various stages of the disease. In the stage of congestion or engorgement, and often before the stage of death is reached, there is a characteristic bronchial cough, and at times there is very little change from the natural breathing. In the stage of red hepatisation the affected side of the chest is seen to expand less freely than the opposite side; there is dullness on
PNEUMONIA

perfusion, and increase of the vocal fremitus; while on auscultation the breath sounds are tubular or bronchial in character, with, in some instances, a perceptible murmur. In certain cases the stage of grey hepatization the percussion note is still dull and the breathing tubular, but crepitations of coarser quality than before are also audible. These various physical signs disappear rapidly following a recovery. With consolidation and resolution of the inflammation the febrile symptoms and rapid breathing continue. The patient during the greater part of the disease lies on the back or on the affected side. The pulse, which at first was full, becomes slow and soft or even feeble. With consolidation the size of the heart varies according to the amount of pulmonary circulation. Occasionally slight jaundice is present, due probably to a similar cause. The urine is scanty, sometimes albuminous, and its chlorides are diminished. In favourable cases, however, the urination may be increased. Sometimes after six or eight days a distinct crisis, marked by a rapid fall of the temperature accompanied with perspiration and with a copious discharge of lachrymæ in the urine. Although no material change is as yet noticed in the physical signs, the patient breathes more easily, sleep returns, and convalescence advances rapidly in the majority of instances. In unfavourable cases death may take place either from the extent of the inflammatory action, especially if the pneumonia is double, from excessive fever, from failure of the heart's action or general strength at about the period of the crisis, or again from the disease assuming from the first a low admixture form with delirium and coma. The death is rapid. The bacteriology of the disease is uncommon. The pneumococcus is frequently present and occasionally the streptococcus, pericarditis and endocarditis, both due to septic poisoning, while perhaps a more frequent complication is bronchitis, which is responsible for a large percentage of the fatal cases. The pneumococcus has been found in the exudate. Secondary pneumonias chiefly follow the specific fevers, as diphtheria, enteric fever, measles and influenza, and are the result of a direct poisoning. Bacteriologically a number of different organisms have been found, together with the specific microbe of the primary disease; the striking features of primary lobar pneumonia are often masked in these types.

The treatment of acute pneumonia has of late undergone a marked change, and may be divided into 3 heads: (1) General hygienic treatment; (2) the treatment of special symptoms; (3) treatment by vaccines and sera. The same treatment of absolute rest should be carried out as in enteric fever; this absolute rest is necessary to limit the auto-inoculation by the absorption of toxins. Fresh air in abundance and even open-air treatment if possible has been attended with good results. Ice poultices over the affected part are useful in the relief of pain, while tepid sponging and tepid or even cold baths may be freely given, and the patient's strength supported by milk, soups and other light forms of nourishment. Stimulants may be called for, and strychnine and digitalin are the most valuable. The treatment, which should be a systolic one, should be carried out. Many trials have been made with antipneumococcal serum, but it has not been shown to have a very marked effect in cutting short the disease. The polyclonal serum of Römer has given the best results. Much more favourable results have been obtained from the use of a vaccine. The results of vaccine treatment obtained by Boellke in 30 cases of severe pneumonia and one case of pneumococcal endocarditis are encouraging. The vaccine, to produce the best effects, should be made from the patient's own pneumococcus, as it is evident there are different strains of pneumococci, the doses (5 to 50 million dead pneumococci) being regulated by the guidance of the eosinohydrex. The objection to the preparation of the vaccine from the patient's own organisms is the time (several days) which is required, valuable time being thereby lost; but the results are much more certain than with the use of a "stock" vaccine.

2. Broncho-Pneumonia (Catarrhal or Lobular-Pneumonia or Capillary Bronchitis). An acute form of lobular pneumonia has been described, having all the characters of acute lobar pneumonia except that the pneumonic patches are disseminated. The term "broncho-pneumonia" is however here used to denote a widespread catarrhal inflammation of the smaller bronchi which spreads in places to the alveoli and produces consolidation. All forms of broncho-pneumonia depend on the invasion of the lung by micro-organisms. No one organism has however been constantly found which can be said to be specific, as in lobar pneumonia; the influenza bacillus, micro-coccus catarrhalis, pneumococcus, Friedländer's bacillus and various staphylococci having been found. John Eyre, in Allbutt's System of Medicine, gives 62% of mixed infection in the cases investigated by him. Broncho-pneumonia may occur as an acute primary affection in children, but is more usually secondary. It may be a sequence of infectious fevers, measles, diphtheria, whooping cough, scarlet fever and sometimes typhoid fever. In these it forms a frequent and often a fatal complication. The large majority of the fatal cases are those of early childhood. In adults it may follow influenza or complicate chronic Bright's disease or various other disorders. Broncho-pneumonia also may follow operations on the mouth or trachea, or the inhalation of foreign bodies into the trachea. It is a frequent complication of pulmonary tuberculosis.

The following changes take place in the lung: at first the affected patches are dense, non-crepitant, with a bluish red appearance tending to become grey or yellow. Under the microscope the air vesicles and finer bronchi are crowded with cells; the result of the inflammatory process, but there is no fibro-necrosis or inflammation in the pneumonic tissue. In favourable cases resolution takes place by fatty degeneration, liquefaction, and absorption of the cells, but on the other hand they may undergo caseous degenerative changes, abscesses may form, or a condition of chronic interstitial pneumonia be developed, in both of which cases the condition passes into one of pulmonary tuberculosis. Evidence of previous bronchitis is usually present in the lungs affected with catarrhal pneumonia. In the great majority of instances catarrhal pneumonia occurs as an accompaniment or sequel of bronchitis, either from the inflammation passing from the finer bronchi to the pulmonary air vesicles, or from its affecting portions of lung which have undergone degeneration.

The symptoms characterizing the onset of catarrhal pneumonia in its more acute form are the occurrence during an attack of bronchitis or the convalescence from measles or whooping cough, of a sudden and marked elevation of temperature, together with a quickened pulse and increased difficulty in breathing. The cough becomes short and painful, and there is little or no expectoration. The physical signs are not distinct, being mixed up with those of the antecedent bronchitis; but, should the pneumonia be extensive, there may be an impaired percussion note with tubular breathing and some bronchophony. Dyspnoea may be present in a marked degree; and death frequently occurs from paralysis of the heart. Broncho-pneumonia is a serious disease, the death-rate in children under 3 years of age has been quoted at 30%.

The treatment of broncho-pneumonia is mainly symptomatic. At the outset a mild purgative is given, and should the secretion accumulate in the bronchial tubes an emetic is useful. Inhalations are useful to relieve the cough, and circulatory stimulants such as strychnine are valuable, together with belladonna and oxygen. When orthopnoea and lividity are present, with distension of the right heart, venesection is necessary. The treatment of broncho-pneumonia by serum and vaccines is not so successful as in lobar pneumonia, owing to the difficulty of ascertaining the precise bacterial infection. The great danger of broncho-pneumonia is the subsequent development of pulmonary tuberculosis.

3. Chronic Interstitial Pneumonia (Cirrhosis of the Lung) is a fibrous change in the lung, chiefly affecting the fibrous stroma and may be either local or diffuse. The changes produced in the lung by this disease are marked chiefly by the growth of nucleated fibroid tissue around the walls of the bronchi and vessels, and in the intervascular septa, which proceeds to such an extent as to invade and obliterate the air cells. The lung, which is at first enlarged, becomes shrunken, dense in texture and solid, any unaffected portions being emphysematous; the bronchi are dilated, the pleura thickened, and the lung substance often deeply pigmented, especially in the case of miners, who are apt to suffer from this disease. The other lung is always greatly enlarged and distended from emphysema; the heart becomes hypertrophied, particularly the right ventricle; and there may be marked atheromatous changes in the
blood vessels. Later the lung becomes converted into a series of bronchiectatic cavities. This condition is usually present to a greater or less degree in almost all chronic diseases of the lungs and bronchi, but it is specially apt to arise in an extensive form from pre-existing catarrhal pneumonia, and is not infrequently occurs in connexion with occupations which necessitate the habitual inhalation of particles of dust, such as those of colliery, road-masons, stonemasons, millers, &c., to which the term pneumonokoniosis is now applied (including broncarcosis, siderosis, chalosis and the so-called "grinder's rot").

The symptoms are very similar to those of chronic phthisis (see TUBERCULOSIS), especially increasing difficulty of breathing, particularly on exertion, cough either dry or with expectoration, sometimes copious and fetid. In the case of coal-miners the system is black from containing carbonaceous matter. The physical signs are deficient expansion of the affected side—the disease being more often upper than lower. The character of the last stages of pulmonary phthisis with colliquative symptoms, increasing emaciation and death. Occasionally dropy is present from the heart becoming affected in the course of the disease. The disease usually terminates in death, though many cases remaining for years in a stationary condition and even undergoing temporary improvement in mild weather, but the tendency is on the whole destructive.

PNOM-PENH, a town of French Indo-China, capital, since 1866, of the protectorate of Cambodia and seat of the resident-superior. Pop. about 60,000, consisting of Cambodians, Annamese, Chinese, Malays, Indians and about 600 Europeans. It is situated on the Mekong about 173 m, from its mouth at the confluence of the ket port. The Annamesian name is Phnem, branch connecting it with the Great Lake (Tonlé-Sap). Its position makes it the market for the products of Cambodia, Laos, Upper Burma and part of Siam (dried fish, rice, cotton, indigo, cardamoms, &c.) The town is lighted by electricity. The palace of the king of Cambodia occupies a large space in the Cambodian quarter. The town gets its name from the Phnom, a central hill surrounded by an ancient pagoda.

PO (anc. Padus, Gr. Πάοδος), a river of northern Italy, and the largest in the whole country, with a total length of about 310 m. direct from the source to the mouth, but, including its many windings, of some 417 m. The navigable portion from Genoa to Genova is also of about 417 m. The length of this portion 636 ft., and its minimum depth 7 ft. Owing to the prevalence of shallows and sandbanks, navigation is difficult.

The Po is the dominating factor in north Italian geography, north Italy practically consisting of the Po basin, with the surrounding slopes of the Alps and Apennines. For a description of its course, and a list of its principal tributaries see ITALY. The area of its basin, which includes portions of Switzerland and Austria, is estimated at 26,798 sq. m.

In the first 21 m. of its course, down to Revello (west of Saluzzo), the Po descends to less than 250 ft., or a fall of 9'-10.100, forming a very remarkable contrast to its fall lower down. From the confluence of the Ticino its fall is about 0'-3.1000; from the beginning of the delta below Ferrara, 0'-08.1000. At Turin it has an average width of 400 to 415 ft., a mean depth of 4 to 5 ft., and a velocity of 1 to 3 ft. in the second. The mean depth from the confluence of the Ticino (altitude 217 ft.) downwards is 6 to 15 ft. The river is embanked from Piacentino, and continues from Cremona, the Po flows for a distance of 600 m. passing through a confined between these high banks, and to the great amount of sedimentary matter which the river brings down with it, its bed has been gradually raised, so that in its lower course it is in many places buried to the surface of the country. Confining the stream between its containing banks is the rapid growth of the delta. Lombardini calculated that the annual increase in the area of the Po-delta during the period of 1300 to 1600 amounted to 127 acres; but during the period 1600 to 1850 it rose to 324 acres. Marini[1] estimated that between the years 1823 and 1893 the annual increase was at the average rate of 173 to 175 acres, and the total accretion at about 20 sq. m.; and the total area inundated last 1893 was about 80,000 acres, with a depth of 6 to 80 m. He further estimated that the Po della Maestra advances 248 ft. annually, the Po delle Tolle 262 ft., the Po della Gnocca 311 ft., and the Po di Gorz 259 ft. The low ground between the Po and the lower Adige and the sea is known as Polesen, a name the derivation of which is much discussed. It is generally applied only to the province of Rovigo, but sometimes extended to the neighbourhood of Adria and Ferrara. All along its course it is bordered (below) by a belt of swamps, and is connected with several of its tributaries by canals, and at the same time other canals connect the tributaries and carry off their waters and the Po to the sea. The total length of the Po is 417 m.

The researches of Helbig (Die Italiacker in der Po-Ebene, Leipzig, 1879) show that the lower valley of the Po was at an early period occupied by people of the Paleolithic and Neolithic stages of civilization, who built themselves houses on the terraces of the streams. It is possible that even they may have begun by crude dikes the great system by which the waters are now controlled; at least it is certain that these works date their origin from pre-Roman antiquity. They refer them to the Etruscans. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the rectangular divisions of the ground, still remarkably distinct, show the military character of some of the agricultural colonies. During the years later, Carian invasions made the protective system was allowed to fall into decay; but the latter part of the middle ages saw the works have regained a great extent. At the time the present arrangement were in existence by the close of the 15th century.

The earlier Roman writers speak of the region between the northern boundaries of Etruria and Umbria and the Alps as Galla (anc. Padus). It was several centuries later that the Po delta was surmounted by the Rubicon being the boundary on the east, and the Arno the boundary on the west, so that, for example, Luca remained outside the boundaries of Italy proper, even in 89 B.C. Romanization had, however, progressed so far that the foundation of colonies and the construction of roads had gone on during the 2nd century, and the whole district as far as the Padus was given the name of the Roman franchise in it, while the Transpadane received Latin rights, and were fully franchised for Roman citizenship. The delta was obviously formed into a province by Sulla in 81 B.C. and continued to be so until the fall of the Republic. The Padus Delta was Boerum (anc. Delos), ort, i.e. the bottomless. The name Padus was taken from the Celts of the Veneti. Thus we find Bodincomagus as a town name (Industria) on the upper course, and Hleda (Padus, Cuta, 95, 7) as a name on one of the mouths of the river. The name Hledos (Erhidane of Greek poetry) was identified with it at a comparatively late period.

POACH (probably from Fr. poche, bag, or Eng. "poke," thrust into), to trespass on private property in pursuit of game or fish; also, generally, to catch game or fish by means of or at times not permitted by the law, or in an unsportsmanlike manner (see GAME LAWS). The etymology is rather obscure, but as used in the independent sense of "poaching" an egg, i.e., breaking into boiling water, the word appears to be from the same original.

POBEDONOSTSEV, CONSTANTINE PETROVICH (1827-1907), Russian jurist, state official, and writer on philosophical and literary subjects. Born in Moscow in 1827, he studied at the School of Law in St Petersburg, and entered the public service as an official in one of the Moscow departments of the senate. From 1860 to 1865 he was professor of Russian civil law in the Moscow University, and instructed the sons of Alexander II. in the theory of law and administration. In 1868 he became a senator in St Petersburg. In 1872 a member of the em, and of the executive board of procurators of the Holy Synod. He always showed himself as a generally compromising Conservative, and never shrink from expressing boldly his opinions. Consequently, in the so-called Liberal camp he was always denounced as an "obscurantist" and an enemy of progress. In the early years of the reign of Alexander II. (1855-1881), Pobédonostsev maintained, though keeping aloof from the Slavophils, that Occidental institutions were radically bad in themselves and totally inapplicable to Russia. Parliamentary methods of administration, modern judicial organization and procedure, trial by jury; freedom of the press, secular education—these were among the principal objects of his aversion. He 1 See G. Marinelli, in Atti ist. rensei sci., 8th series, vol. viii. (1865-1867); and "L'Accrescimento del Delta del Po nel Negro Secolo XIX," in Riv. Geol. Ital. (1898), vol. v.
subjected all of them to a severe analysis in his Reflections of a Russian Statesman (English by R. C. Long, London, 1898).

To these dangerous products of Occidental rationalism he found a counterpoise in popular vis inertiae, and in the respect of the masses for institutions developed slowly and automatically during the past centuries of national life. Among the practical deductions drawn from these premises is the necessity of preserving the autocratic power, and of fostering among the people the traditional veneration for the ritual of the national Church. In the sphere of practical politics he exercised considerable influence by inspiring and encouraging the Russification policy of Alexander III. (1881-1894), which found expression in an administrative Nationalist propaganda and led to a good deal of religious persecution. After the death of Alexander III. he lost much of his influence, for Nicholas II., while clinging to his father’s Russification policy and even extending it to Finland, disliked the idea of systematic religious persecution, and was not wholly averse from the partial emancipation of the Russian Church from civil control. During the revolutionary tumult which followed the disastrous war with Japan Pobé-donostsev, being nearly 80 years of age, retired from public and political life.

POCHARD, POCKET-MOUSE

1 names properly belonging to the male of a species of duck (the female of which is known as the Dunbird), the Anas ferina of Linnaeus, and Nyroca ferina of later ornithologists—but names very often applied by writers in a general way to most of the group or sub-family Fuligulinae, commonly called Diving or Sea-Ducks (see DUCK). The Pochard in full plumage is a very handsome bird, with a coppery-red head, on the sides of which sparkle the ruby irides of his eyes, relieved by the greyish-blue of the basal half of his broad bill, and the deep black of his breast, while his back and flanks appear of a light grey, being really of a dull white closely barred by fine undulating black lines. The back-coverts above and below are black, the quill feathers brownish-black, and the lower surface of a dull white. The Dunbird has the head and neck reddish-brown, with ill-defined whitish patches on the cheeks and chin; the back and upper tail-coverts are dull brown, and the rest of the plumage, except the lower tail-coverts, which are brownish-grey, resembles that of the Pochard. This species is very abundant in many parts of Europe, northern Asia, and North America, generally frequenting in winter the larger open waters, and extending its migrations to Barbary and Egypt, but in summer retiring northward and inland to breed. The American Pochard is slightly larger, has yellow eyes, and is now regarded as specifically distinct under the name of Nyroca americana; but America has a perfectly distinct though allied species in the celebrated canvas-back duck, N. valliseria, a much larger bird, with a longer, higher and narrower bill, which has no blue at the base, and, though the plumage of both, especially in the females, is very similar, the male canvas-back has a darker head, and the black lines on the back and flanks are much broken up and farther asunder, so that the effect is to give these parts a much lighter colour, and from this has arisen the bird’s common though fanciful name. Its scientific epithet is derived from the fresh-water plant, a species of Valliseria, usually known as “widgeon grass.” The male’s fleshless beak is believed to acquire the delicate flavour that is held in so great a repute. The Pochard and Dunbird in Europe are in much request for the table (as the German name of the species, Tafelente, testifies) when they frequent fresh-water; birds killed on the sea-coast are so rank as to be almost worthless.

Among other species nearly allied to the Pochard that frequent the northern hemisphere may be mentioned the Scapu-duck, Fuligula marila, with its American representative F. affinis, in both of which the male has the head black, glossed with blue or green; but these are nearly always uneatable from the nature of their food, which is mostly gathered at low tide on the “scapu- or scate,”—the banks on which mussels grow and are (see Muscidae) products. The Tufted Duck, F. cristata—black with a crest and white flanks—and its American equivalent F. colberti, and the White-eyed Pochard, F. penelope, and the F. rubripes of the Old World, and well known in India. In the southern hemisphere the genus is represented by three species, F. capensis, F. rufus and F. nova-zealandiae, whose names indicate the country each inhabits, and in South America exists a somewhat divergent form which has been placed in a distinct genus as Metopiana peposa.

POCKET-MOUSE, the small group known as the Eiders, which differ from them in several respects: the bulk at the base of the traheal in the male, so largely developed in the members of the genus Fuligula, is here much smaller and wholly of bone; the males take a much longer time, two or even three years, to attain their full plumage, and some of the feathers on the head, when that plumage is completed, are almost stiff, glintening and of a peculiar pole-green colour. This little group of hardly more than half a dozen species may be fairly considered to form a separate genus under the name of Somateria. Many authors indeed have—unjustly, as it seems to the present writer—broken it up into several genera and sub-genera. The Eider, S. mollissima, is the largest of this group, and, beautiful as it is, has lost its generality by the King-Duck, S. spectabilis, and the little S. stelleri. A most interesting form generally, but obviously in error, placed among the Eiders, is the Logone clergyi, or the “Sword-Bill” (or more probably Tachyeres) cinerus of Chile, the Falkland Islands and Straits of Magellan—nearly as large as a tame goose, and subject to, as far as known, unique peculiarity of losing its power of flight. It is generally reckoned that this species was described by C. Darwin in his Journal of Researches, and its anatomy is the subject of an excellent paper in the Zoological Society’s Transactions (viii. 433-501, pls. xviii.-lxii.) by R. O. Cunningham.

POCKET, a small bag, particularly a bag-like receptacle either fastened to or inserted in an article of clothing. As a measure of capacity “pocket” is now only used for hops; it equals 16 lb. The word appears in Mids. Eng. as pokel, and is taken from a Norman diminutive of O. Fr. poke, pouke, mod. poche, cf. “pouch.” The form “poke” is now only used dialectically, or in such proverbial sayings as “a pig in a poke,” and possibly in the “poke-bonnet,” the coal-scuttle bonnet fashionable during the first part of the 19th century, and now worn by the female members of the Salvation Army; more precisely its name is the diminutive of “poket,” applying to the hole to thrust forward, dig. The origin of this is obscure. Dutch has poken, pokk, a dagger; Swedish pokel, a stick.

POCKET-GOPHER (i.e. pouched rat), the name of a group of chiefly North, American rat-like rodents, characterized by the possession of large cheek-pouches, the openings of which are external to the mouth; while their inner surface is lined with fur. The cheek-teeth, which comprise two pairs of premolars and three of molars in each jaw, are in the form of simple prisms of enamel, which do not develop roots. The fore and hind limbs are of approximately equal length, but the second and third front-claws are greatly enlarged, and all the claws are furnished at the base with bristles. The eyes are small, and the external ears rudimentary. 

Pocket-gophers, which typify a family, the Geomyidae, spend the whole of their time underground, and are specially organized for such a mode of existence, their powerful claws being firmly gnawed for digging, with their toes on the toes prevent the earth from passing between them. The toes are well adapted to loosen the ground, like a fork; and the little rodents are able to move both backwards and forwards in their runs. The cheek-teeth are employed chiefly in carrying food, which consists largely of roots. In the typical genus Geomys the upper incisors are grooved, but in the allied Thomomys they are smooth. The common pocket-gopher, Geomys bursarius, of the Mississippi Valley measures about 5 in. long, with no overlong tail, which is about 1 in. long, and rufous brown and greyish beneath. A well-known representative of the second genus is Thomomys talpoides, which is considerably smaller than the former. To the farmer and the gardener pocket-gophers are an unmitigated source of annoyance. (See RODENTIA.)

POCKET-MOUSE, the name of a number of small jerboa-like, chiefly North, American rodents belonging to the family Geomyidae, and constituting the genus Perognathus and Heteromyx. They are nearly allied to the American kangaroo-rats (see
POCOCK—PODEBRAD

KANGAROO-RA], but differ in having rooted molar teeth. The typical pocket-mouse P. fasciatus, which is a native of Montana, Missouri, and Wyoming, is a sandy-coloured rodent marked with black lines above and with white beneath, and measuring about 6 in. in length, this length being equally divided between the head and body and the tail. (See Rodentia.)

POCOCK, SIR GEORGE (1706-1792). British admiral, son of Thomas Pocock, chaplain in the navy, was born on the 6th of March 1706, and entered the navy under the protection of his maternal uncle, Captain Streynsham Master (1652-1724), in the "Superbe" in 1718. He became lieutenant in 1725, commander in 1733, and post-captain in 1738. After serving in the West Indies he was sent to the East Indies in 1754 as captain of the "Cumberland" (58) with Rear-Admiral Charles Watson (1714-1757). Watson's squadron co-operated with Clive in the conquest of Bengal. In 1755 Pocock became rear-admiral, and was promoted vice-admiral in 1756. On the death of Watson he took the command of the naval forces in the eastern seas. In 1758 he was joined by Commodore Charles Steevens (d. 1761), but the reinforcement only raised the squadron to seven armed ships. He believed his squadron was in the best position to press between France and England. The French sent a naval force from their islands in the Indian Ocean into the Bay of Bengal to the assistance of Pondicherry. To intercept the arrival of these reinforcements for the enemy now became the object of Pocock. The French force was indeed of less intrinsic strength than his own. Count D'Aché (1700-1775), who commanded, had to make up his line by including several Indiamen, which were only armed merchant ships. Yet the number of the French was superior and Pocock was required by the practice of his time to fight by the old official fighting instructions. He had to bring his ships into action in a line with the enemy, and to preserve his formation while the engagement lasted. All Pocock's encounters with D'Aché were indecisive. The first battle, on the 29th of April 1758, failed to prevent the Frenchmen from reaching Pondicherry. After a second and more severe engagement on the 3rd of August, the French admiral returned to the Mauritius, and when the monsoon set in Pocock went round to Bombay. He was back early in spring, but the French admiral did not return to the Bay of Bengal till September. Again Pocock was unable to prevent his opponent from reaching Pondicherry, and a well-contested battle between them on the 10th of September 1759 proved indecisive. The French were then in a very difficult position, and D'Aché could get no stores for his squadron. He was compelled to return to the islands, and the English were left in possession of the Coromandel and Malabar coasts. Pocock went home in 1760, and in 1761 was made Knight of the Bath and admiral. In 1762 he was appointed to the command of the naval forces in the combined expedition which took Havana. The siege, which began on the 7th of June, and lasted till the 13th of August, was rendered deadly by the climate. The final victory was largely attributable to the vigorous and intelligent aid which Pocock gave to the troops. His share in the prize money was of less interest (212,600). On his return to England Pocock is said to have been disappointed because another officer, Sir Charles Saunders (1713-1775), was chosen in preference to himself as a member of the admiralty board, and to have resigned in consequence. It is certain that he resigned his commission in 1766. He died on the 3rd of April 1792. His monument is in Westminster Abbey.

POCOCKE, EDWARD (1604-1691), English Orientalist and biblical scholar, was born in 1604, the son of a Berkshire clergyman, and received his education at the free school of Thame in Oxfordshire and at Corpus Christi College, Oxford (scholar in 1620, fellow in 1628). The first-fruit of his studies was an edition (1633) of the New Testament in Greek from the original MS. Pococke is said to have appealed to the Parthenopean canon (2 Peter 2 and 3 John, Jude) which were not in the old Syriac canon, and were not contained in European editions of the Peshito. This was published at Leiden at the instigation of G. Vossius in 1630, and in the same year Pocock sailed for Aleppo as chaplain to the English factory. At Aleppo he made himself a profound Arabic scholar, and collected many valuable MSS. At this time Wm. Laud was bishop of London and chancellor of the university of Oxford, and Pocock became known to him as one who could help his schemes for enriching the university. Laud founded an Arabic chair at Oxford, and invited Pocock home to fill it, and he entered on his duties on the 10th of August 1636; but next summer he sailed again for Constantinople to prosecute further studies and collect more books, and remained there for about three years. When he returned to England Laud was in the Tower, but had taken the precaution to place the Arabic chair under a permanent footing. Pocock does not seem to have been an extreme churchman or to have meddled actively in politics. His rare scholarship and personal qualities raised him up influential friends among the opposite party, foremost among these being John Selden and John Owen. Through their offices he was even advanced in 1648 to the chair of Hebrew, though as he could not take the engagement of 1640 he lost the emoluments of the post soon after, and did not recover them till the Restoration. These cares seriously hampered Pocock in his studies, as he complains in the preface to his Eutychius; he seems to have felt deeply the attempts to remove him from his parish of Childrey, a college thing which he had accepted in 1642. In 1649 he published the Specimem historiarium arabum, a short account of the origin and manners of the Arabs, taken from Barhebræus (Abulfaragius), with notes from a vast number of MS, sources which are still valuable. This was followed in 1655 by the Porta Mosis, extracts from the Arabic commentary of Maimonides on the Mishna, with translation and very learned notes; and in 1656 by the annals of Eutychius in Arabic and Latin. He also gave active assistance to Brian Walton's polyglot bible, and the preface to the various readings of the Arabic Pentateuch is from his hand. After the Restoration Pocock's political and pecuniary troubles were removed, but the reception of his Magnum opus—a complete edition of the Arabic history of Barbebræus (Greg. Abulfaragii historiae compendiosa dynastiarum), which he dedicated to the king in 1663, showed that the new order of things was not very favourable to profound scholarship. After this his most important works were a Lection heplagion (1669) and English commentaries on Micah (1677), Malachi (1677), Hosea (1685) and Joel (1691), which are still worth reading. An Arabic translation of Grotius's De viritate, which appeared in 1660, may also be mentioned as a proof of Pocock's interest in the propagation of Christianity in the East. This was an old plan, which he had talked over with Grotius at Paris on his way back from Constantinople. Pocock married in 1646, and died in 1691. One of his sons, Edward (1648-1727), published several contributions to Arabic literature—a fragment of Abdallatif's description of Egypt and the Philosophus autodidactus of Ibn Tufail.

The theological works of Pococke were collected, in two volumes, in 1746, with a curious account of his life and writings by L. Twells.

PODEBRAD, GEORGE OF (1420-1471), king of Bohemia, was the son of Victoria of Kunstat and Podebrad, a Bohemian nobleman, who was one of the leaders of the "Orphans" or modern Podebrad party in the Hussite wars. George himself as a boy of fourteen took part in the great battle of Lipo, which marks the downfall of the more advanced Taborites. Early in life, as one of the leaders of the Calixtine party, he defeated the Austrian troops of the German King Albert II., son-in-law and successor of King Sigismund. He soon became a prominent member of the national or Calixtine party, and after the death of Ptacek of Pirkstein its leader. During the minority of Ladislas, son of Albert, who was born after his father's death, Bohemia was divided into two parties—the Romanist or Austrian one, led by Ulrich von Rosenberg (1493-1452), and the national one, led by Podebrad. After various attempts at reconciliation, Podebrad determined to appeal to the force of arms. He gradually raised an armed force in north-eastern Bohemia, where the Calixtine cause had most adherents and where his ancestral castle was situated. With this army, consisting of about 9000 men, he marched in 1448 from Kutna Hora to Prague, and obtained possession of the capital almost without resistance. Civil war, however, broke
out, but Poděbrad succeeded in defeating the Romanist nobles. In 1451 the emperor Frederick III., as guardian of the young king Ladislas, entrusted Poděbrad with the administration of Bohemia. In the same year a diet assembled at Prague also conferred on Poděbrad the regency. The struggle of the Bohemians against Rome continued uninterruptedly, and the position of Poděbrad became a very difficult one when the young king Ladislas, who was crowned in 1453, expressed his sympathies for the Roman Church, though he had recognized the compacts and the ancient privileges of Bohemia. In 1457 King Ladislas died suddenly, and public opinion from an early period accused Poděbrad of having poisoned him. The Bohemian historian, Palacky, fifty years ago thoroughly disproved this accusation, and, though it has recently been revived by German historians, it must undoubtedly be considered as a calumny. On the 27th of February 1458 the estates of Bohemia unanimously chose Poděbrad as king; even the adherents of the Austrian party voted for him, not wishing at that moment to oppose the popular feeling, which demanded the election of a national sovereign. A year after the accession of Poděbrad Pius II. (Aeneas Sylvius) became pope, and his incessant hostility proved one of the most serious obstacles to Poděbrad's rule. Though he rejected the demand of the pope, who wished him to consent to the abolition of the compacts, he endeavoured to carry-favour with the Roman see by punishing severely all the more advanced opponents of papacy in Bohemia. Poděbrad's persecution of the newly-founded community of the Bohemian brethren is certainly a blemish on his career. All Poděbrad's endeavours to establish peace with Rome proved ineffectual, and though the death of Pius II. prevented him from carrying out his planned crusade against Bohemia, his successor was a scarcely less bitter enemy of the country. Though the rule of Poděbrad had proved very successful and Bohemia had under it obtained a degree of prosperity which had been unknown since the time of Charles IV., the Cälkinte king had many enemies among the Romanist members of the powerful Bohemian nobility. The malcontent nobles met at Zelema Hora (Griineberg) on the 28th of November 1465, and concluded an alliance against the king, bringing forward many—mostly untrue—accusations against him. The confederacy was from its beginning supported by the Roman see, though Poděbrad after the death of his imposable enemy, Pius II., attempted to negotiate with the new pope, Paul II. These negotiations ended when the pontiff grossly insulted the envoys of the king of Bohemia. On the 23rd of December 1466 Paul II. excommunicated Poděbrad and pronounced his deposition as king of Bohemia, forbidding all Romanists to continue in his allegiance. The emperor Frederick III., and King Matthias of Hungary, Poděbrad's former ally, joined the insurgent Bohemian nobles. King Matthias conquered a large part of Moravia, and was crowned in the capital of that country, Brno (Brünn), as king of Bohemia on the 3rd of May 1469. In the following year Poděbrad was more successful in his resistance to his many enemies, but his death on the 22nd of March 1471 put a stop to the war. In spite of the misfortunes of the last years of his reign, Poděbrad's memory has always been cherished by the Bohemians. He was the only king of Bohemia who belonged to that nation, and the only one who was not a Roman Catholic.

See H. Markgraf, Über das Verhältnisse des Königs Georg von Podébrad zu Papst Pius II. (1867); Jordan, Das Königlum Georg von Podébrad (1861); A. Bachmann, Ein Jahr hohemich Geschicht (1876), and Urkunden ... der österreichischen Geschichte ... im Zeitalter Georg von Podébrad (1879); E. W. Kanter, Die Ermordung König Ladislaus (1900); Novotny, Über den Tod König Ladislaus (1906). All histories of Bohemia, particularly that of F. Palacky (1856-1897), contain detailed accounts of the career of King George of Podébrad.

PODĚSTÁ (Lat. poteslas, power), the name given during the later middle ages to a high official in many Italian cities. Podestās or rectors were first appointed by the emperor Frederick I. when about 1158 he began to assert his Imperial rights over the cities of northern Italy. Their business was to enforce these rights; from the first they were very unpopular, and their arbitrary behaviour was a factor in bringing about the formation of the Lombard league and the rising against Frederick in 1157.

Although the emperor's experiment was short-lived podestās soon became general in northern Italy, making their appearance in most communes about 1200. These officials, however, were now appointed by the citizens or by their representatives. They exercised the supreme power in the city, both in peace and war, both in foreign and domestic matters, but they only held office for a period of a year. In order to avoid the intestine strife so common in Italian civic life, it soon became the custom to select a stranger to fill this position. Venetians were in the first instance asked to supply the office during the 13th and 14th centuries, probably because at this time, at least, they were less concerned than other Italians in the affairs of the mainland. Afterwards in a few cases the term of office was extended to cover a period of years, or even a lifetime.

During the later part of the 12th and the whole of the 13th century most of the Italian cities were governed by podestās. Concerning Rome, Gregorovius says that in 1205 "the pope changed the form of the civic government; the executive power lying henceforward in the hands of a single senator or podestā, who, directly or indirectly, was appointed by the pope." In Florence soon after 1180 the chief authority was transferred from the consuls to the podestā, and Milan and other cities were also ruled by these officials. There were, moreover, podestās in some of the cities of Provence. Gradually the podestās became more despotic and more corrupt, and sometimes a special official was appointed to hear complaints against them; in the 13th century in Florence and some other cities a capitano del popolo was chosen to look after the interests of the lower classes. In other ways also the power of the podestās was reduced; they were confined more and more to judicial functions until they disappeared early in the 16th century.

The officials who were sent by the Italian republics to administer the affairs of dependent cities were sometimes called podestās. At the present day the cities of Trent and Trieste give the name of podestā to their chief magistrate.

The example of Italy in the matter of podestās was sometimes followed by cities and republics in northern Europe in the middle ages, notably by such as had trade relations with Italy. The officers thus elected sometimes bore the title of podestā or podestat. Thus in East Friesland there were podestās identical in name and functions with those of the Italian republics; sometimes each province had one, sometimes the federal diet elected a podestā-general for the whole country, the term of office being for a limited period of for life (see J. L. Motley, Dutch Republic, i. 44, ed. 1903).

Lists of the Italian podestās are given in Stekov, Manuel d'histoire; voir liii. (Leiden, 1889). See also W. F. Butler, The Lombard Communities (1906).

PODGORITSA (Croatian, Podgorica), the largest town in Montenegro; on the left bank of the river Moracha, and in a fertile valley which strikes inland for 18 m. from the shores of Lake Scutari to the mountains of central and eastern Montenegro. Pop. (1900), about 5500. Spread out on a perfectly flat plain, Podgoritsa has two distinct parts: the picturesque Turkish quarter, with its mosques and ruined ramparts, and the Montenegrin quarter, built since 1877, and containing a prison and an agricultural college. These quarters are separated by the river Ribnita, a tributary of the Moracha. A fine old Turkish bridge crosses the main street. Podgoritsa receives from the eastern plains and the north-eastern highlands a great quantity of tobacco, fruit, cereals, honey, silk, livestock and other commodities, which it distributes through Plavitsa, its port on Lake Scutari, and through Cattaro to Cattaro. After being captured from Turkey in 1877, Podgoritsa was in 1878 recognized as Montenegro territory by the Treaty of Berlin.

PODUIUM (Gr. ποδόσωμα, diminutive of πόσω, foot), the name in architecture for a continuous pedestal, or low wall on which columns are carried, consisting of a cornice or capping, a dado or die, and a moulded plinth. In the Etruscan and Roman temples
the whole structure was raised on a podium, with a flight of steps on the principal front, enclosed between the prolongation of the podium wall.

**PODOLIA**, a government of south-western Russia, having Volhynia on the N., Kievo and Kherson on the E. and S., Bessarabia on the S.W., and Galicia (Austria) on the W., from which it is separated by the Zbrucz, or Rodvocha, a tributary of the Dniester. It has an area of 16,219 sq. m., extending for 200 m. from N.W. to S.E. on the left bank of the Dniester. In the same direction the government is traversed by two ranges of hills separated by the Bug, ramifications of the Avrjatsk heights. These hills nowhere exceed an elevation of 115 ft. Two large rivers, which numerous tributaries, drain the government—the Dniester, which forms its boundary with Bessarabia and is navigable throughout its length, and the Bug, which flows almost parallel to the former in a higher, sometimes swampy, valley, and is interrupted at several places by rapids. The Dniester is an important channel for trade, corn, spirits and timber being exported from Mogilev, Kalus, Zhvanets, Poporg and other Podolian river-ports. The rapid smaller tributaries of the Dniester supply numerous flour-mills with motive power. The soil is a sandy loam, often black, and produces one of the most fertile governments of Russia. Forests cover nearly 15% of the total area. Marshes occur only beside the Bug. The climate is moderate, the average temperature of the year at Kamenets being 48°5 (24° 5 in January, 69° in July). The estimated population in 1906 was 3,543,700. It consists chiefly of Little Russians, Poles (34%), and Jews (12%). There are besides a few Armenians, some Germans, and 50,000 Moldavians. There are many Nonconformists (18,000) among the Russians, Tulchin being the seat of their bishops and a centre of propaganda. After Moscow, Podolia is the most densely inhabited government of Russia outside Poland. It is divided into twelve districts, the chief towns of which are Bratslav, Podol'sk, the capital, Balta, Bratslav, Gaisin, Letichev, Litin, Mogilev-on-Dniester, Novaya-Ushitsa, Olgopol, Proskurov, Vinnitsa and Yampil. The chief occupations of the people are agriculture and gardening. The principal crops are wheat, rye, oats, barley, maize, hemp, flax, potatoes, beetroot and tobacco. Podolia is famous for its cherries and mulberries, its melons, gourds and cucumbers. Nearly 67,000 gallons of wine are obtained annually. Large numbers of horses, cattle and sheep are bred, the cattle being famous. Bee-keeping is an important industry. Sugar factories, distilleries, flour-mills, wooden mills, tanneries, potteries, tobacco factories, candle and soap factories, have an annual output valued at £3,000,000. An active trade is carried on with Austria, especially through the Isakovets and Gusyatin custom-houses, corn, cattle, horses, skins, wool, linseed and hemp seed being exported, in exchange for wooden wares, linen, woollen stuffs, cotton, glass and agricultural implements. The trade with the interior is also carried on very briskly, especially at the twenty-six fairs, the chief of which are Balta and Yarmolintsy. Podolia is traversed by a railway which runs parallel to the Dniester, from Lemberg to Odessa, and has two branch lines, to Kiev (from Zhmirkina) and to Poltava (from Balta).

**History.** The country has been inhabited since the beginning of the Christian period. Herodotus mentions it as the seat of the Graeco-Scythian Alazones and the Scythian Neuri, who were followed by the Dacians and the Getae. The Romans left traces of their rule in the Wall of Trajan, which stretches through the modern districts of Kamenets, Ushitsa and Proskurov. During the great migrations many nationalities passed through this territory, or settled within it for some time, leaving traces in numerous archaeological remains. Nestor mentions that the Bujanes and Dulebes occupied the Bug, while the Tvertsi and Uglishes, apparently all four Slav tribes, were settled on the Dniester. These peoples were conquered by the Avars in the 7th century. Oleg, prince of Kiev, extended his rule over this territory—the Pontizhe, or "lowlands," which became later a part of the principalities of Volynia, Kiev and Galicia. In the 13th century the Pontizhe was plundered by the Mongols; a hundred years afterwards Olgierd, prince of Lithuania, freed it from their rule, annexing it to his own territories under the name of Podolia, a word which has the same meaning as Ponizhe. After the death (1430) of the Lithuanian prince Vitovt, Podolia was annexed to Poland, with the exception of its eastern part, the province of Bratslav, which remained under Lithuania until its union (1561) with Poland. The Poles retained Podolia until the third division of their country in 1793, when it was taken by Russia.

(P. A. K.; J. T. B. E.)

**POZDOLSK**, a town of Russia, in the government of Moscow, 26 m. S. of the city of Moscow, at the junction of the two main roads from Moscow to the Crimea and to Warsaw. Pop. (1881), 11,000; (1897), 3,808. It is picturesquely built on the hilly banks of the Pakhra, here crossed by a suspension bridge for carriages as well as by the railway bridge. Down to 1781 the wealthy village of Podol was a dependency of the Danilov monastery in Moscow. Before the opening of the southern railway the caravans of wagons and sledges to and from Moscow used to halt here; the principal occupation of the inhabitants was in keeping and supplying the caravans with provisions and other necessaries of travel. The limestone quarries, at the confluence of the Pakhra, supply the capital with good building material; and there are a cement, lime and brick factory and a paper-mill.

**PODOPHYLIN**, a drug obtained from the rhizome of the American mandrake or may apple, Podophyllum peltatum, an herbaceous perennial belonging to the natural order Berberidaceae, indigenous in woods in Canada and the United States. The plant is about 1 ft. high, bearing two peltate, deeply-divided leaves, which are about 5 in. in diameter, and bear in the axil a solitary, stalked, white flower, about the size and shape of the garden anemone, with six or more petals and twice as many hypogynous stamens. The fruit is ripe in July, and is a two-celled, yellowish, berry, containing two seeds, each surrounded by a pulpy outer coat or aril. The rhizome, as met with in commerce, occurs in cylindrical pieces 2 or 3 in. long and about $\frac{1}{2}$ in. in diameter, of a chocolate or purplish-brown colour, smooth, and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odour is heavy and disagreeable, and the taste acid and bitter.

Podophyllin is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. It varies in colour from greyish to bright yellow. The greenish-brown, the first-named being the better. The powder is soluble in alcohol and strong solutions of alkalis, such as ammonia. Its composition is somewhat complex. There are certainly at least two resins in it: a picro-podophyllin resin of them being soluble and the other insoluble in ether. Each of these contains an active substance, which can be obtained in crystalline form, and is known as podophyllotoxin. It is soluble in alcohol, ether, chloroform and boiling water. Alkalis decompose it into picro-podophyllin acid and picro-podophyllin, minute traces of both of which occur in a free state in the rhizome. The acid is inert, but picro-podophyllin is the active principle. It is a crystalline body, soluble only in concentrated alcohol. Hence the inutility of the pharmaceutical tinctura podophylli, which cannot be diluted before administration. The properties of podophyllin resin vary with the reaction of the tissues in which it is in contact; where this is acid the drug is inert, the picro-podophyllin being precipitated.

The resin does not affect the unbroken skin, but may be absorbed from a raw surface, and will then cause purging. When taken internally it is both a secretory and an excretory chologogue, but so irritant and powerful that its use in cases of jaundice is generally undesirable. Its value, however, in certain cases of constipation of hepatic origin is undeniable. When used in tinctures, usually mixed with aloe. The best method of prescribing podophyllin is in pill form. In toxic doses podophyllin causes intense enteritis, with all its characteristic symptoms, and severe depression, which may end in death. The treatment is symptomatic, there being no specific antidote.

**POE, EDGAR ALLAN** (1809-1849), American poet, writer of fiction and critic, was born at Boston, Massachusetts, on the 19th of January 1809. The family was of English origin, but was settled in Ireland, whence the poet's great-grandfather emigrated to Maryland. His grandfather, David Poe, served with credit as a
soldier in the War of Independence, was known to Washington, and was the friend of Lafayette. His son David Poe was bred as a lawyer, but deeply offended his family by marrying an actress of English birth, Mrs Elizabeth Hopkins, née Arnold, and by himself going on the stage. In 1811 he and his wife died, leaving three children—William, Edgar, and a daughter Rosalie—wholly destitute. William died young, and Rosalie became mad. Edgar was adopted by John Allen, a tobacco merchant of Scottish extraction, seemingly at the request of his wife, who was childless. The boy was indulged in every way, and encouraged to believe that he would inherit Mr Allan's fortune. Mr Allan, having come to England in 1815, placed Edgar in a school at Stoke Newington, kept by a Dr Bransby. In 1820 Mr Allan returned to Richmond, Virginia, and Edgar was first placed at school in the town and then sent to the university of Virginia at Charlottesville in 1826. Here the effects of a very unwise training on a temperament of inherited neurotic tendency were soon seen. He was fond of athletics, and was a strong and ardent swimmer; but he developed a passion for gambling and drink. His disorders made it necessary to remove him, and he was taken away by Mr Allan, who refused to pay his debts of honour. He enlisted on the 26th of May 1827 at Boston, and served for two years in the United States army. As a soldier his conduct must have been exemplary, for he was promoted sergeant-major on the 5th of January 1829. It is to be noted that throughout his life, when under orders, Poe could be a diligent and capable subordinate. In May 1829 Mr Allan secured his discharge from the army, and in 1830 obtained a nomination for him to the West Point military academy. As a student he showed considerable faculty for mathematics, but his aloofness prevented him from being popular with his comrades, and he neglected his duty. When court-martialed he made no answer to the charges, and was expelled on the 6th of March 1831. Mr Allan's generosity was now exhausted. The death of his first wife in 1829 had doubtless removed an influence favourable to Poe. A second marriage brought him children, and at his death in 1834 he left his adopted son nothing. A last meeting between the two, shortly before Mr Allan's death, led only to a scene of painful violence. In 1827 Poe had published his first volume of poetry, _Tamerlane and other Poems_, at Boston. He did not publish under his name, but as "A Bostonian." In 1831 he published a volume of _Poems_ under his name at New York. His life immediately after he left West Point is very obscure, but in 1833 he was living at Baltimore with his paternal aunt, Mrs Clemm, who was throughout life his protector, and, in so far as extreme poverty permitted, his support. In 1835 he won a prize of $100 offered for the best essay by the Baltimore _Saturday Visitor_. He had not, however, won the prize for the best poem if the judges had not thought it wrong to give both rewards to one competitor. The story, _MS. found in a Bottle_, is one of the most mediocre of his tales, but his success gave him an introduction to editors and publishers, who were attracted by his striking personal appearance and his fine manners, and were also touched by his manifest poverty. From 1833 till his death he was employed on different magazines at Richmond, New York and Philadelphia. His famous poem "The Raven" was published first in 1845, and soon became extraordinarily popular; but Poe only got £3 for it. The facts of his life have been the subject of very ill-judged controversy. The acrimonious tone of the biography by Rufus Griswold, prefixed to the first collected edition of his works in 1850, gave natural offence, and attempts have been made to show that the biographer was wrong as to the facts. But it is no real kindness to Poe's memory to deny the sad truth that he was subject to chronic alcoholism. He was not a boon companion, and never became callous to his vice. When it seized him he drank raw spirits, and was disordered by a very little. But when he was free from the maddening influence of alcohol he was gentle, well-bred, and a hard worker on the staff of a magazine, willing and able to write reviews, answer correspondents, propose riddles or invent and solve cryptograms. His value as a contributor and sub-editor secured him successive engagements on the _Southern Literary Messenger_ of Richmond, on the _New Quarterly Review_, and on _Graham's Magazine_ at Philadelphia. It enabled him in 1843 to have a magazine of his own, the _Stylus_. His mania sooner or later broke off all his engagements and ruined his own venture. In 1845 he married his cousin, Virginia Clemm, a beautiful girl of fourteen years of age. A false statement as to her age was made at the time of the marriage. She died after a long decline in 1847. Poe made two attempts to marry women of fortune—Mrs Whitman and Mrs Shelton. The first of these engagements was broken off. The second was terminated by his death in hospital at Baltimore, Md., on the 7th of October, and the constitution of the country. His life and death had many precedents, and will always recur among Bohemian men of letters and artists. What was individual in Poe, and what alone renders him memorable, was his narrow but profound and original genius (see _American Literature_). In the midst of much hack-work and not a few failures in his own field he produced a small body of verse, and a handful of short stories of rare and peculiar excellence. The poems express a melancholy sensuous emotion in a penetrating melody all his own. The stories give form to horror and fear with an exquisite exactness of touch, or construct and unravel mysteries with extreme dexterity. He was a conscientious literary artist of the first rank, and would have been a great one, though often commonplace and sometimes ill-natured, as when he attacked Longfellow for plagiarism, was trenchant and sagacious at his best.

_Bibliography._—The _Life and Letters of Edgar Allan Poe_, by J. A. Harrison (New York, 1903), and _The Life and Letters of Edgar Allan Poe_ (Boston, new ed. 1909), by G. E. Woodberry, are the best biographies. The standard edition of his _Works_ is that published in 1894-1895 by Chicago, in ten volumes, by E. C. Stedman and G. E. Woodberry. There have been many partial reprints. For Poe's influence in France, which has been great, see C. Baudelaire, _Histoires extraordinaires_ (Paris, 1857); S. Mallarmé, _Poèmes d'Edgar Poe_ (Brussels, 1888); and _Les Névrosés_, by Arvédie Barine (Paris, 1889). (D.H.)

**POERIO, ALESSANDRO** (1802–1848), Italian poet and patriot, was descended from an old Calabrian family, his father, Baron Giuseppe Poerio, being a distinguished lawyer of Naples. In 1815 he and his brother Carlo accompanied their father, who had been identified with Murat's cause, into exile, and settled at Florence. In 1818 they were allowed to return to Naples, and on the proclamation of the constitution in 1820 the Poerios were among the stoutest defenders of the newly-won freedom. Alessandro fought as a volunteer, under General Guglielmo Pepe, against the Austrians in 1821, but when the latter reoccupied Naples on the king's restoration to the constitution, the family was again exiled and settled at Gratz. Alessandro devoted himself to study in various German universities, and at Weimar he became the friend of Goethe. In 1835 the Poerios returned to Naples, and Alessandro, while practising law with his father, published a number of lyrics. In 1848 he accompanied Pepe as a volunteer to fight the Austrians in northern Italy, and on the recall of the Neapolitan contingent Alessandro followed Pepe to Venice and displayed great bravery during the siege. He was severely wounded in the fighting round Mestre, and died on the 3rd of November 1848. His poetry "reveals the idealism of a tender and delicate mind which was diligent in storing up sensations and images that for others would have been at most the transient impressions of a moment." But he could also sound the clarion note of patriotism, as in his stirring poem *Il Risorgimento.*

His brother Carlo (1803–1867), after returning to Naples, practised as an advocate, and from 1837 to 1848 was frequently arrested and imprisoned; but when King Ferdinand, moved by the demonstration of the 27th of January of the latter year, promulgated a constitution, he was made minister of education. Discovering, however, that the king was acting in bad faith, he resigned office in April and returned to Naples to take his seat in parliament, where he led the constitutional opposition. The Austrian victory of Novara (March 1849) set the king free to dissolve parliament and trample on the constitution, and on the 19th of July 1849 Poerio was arrested, tried, and condemned to
nineteen years in irons. Chained in pairs, he and other political
prisoners were confined in one small room in the bagno of Nisida,
near the lazaretto. The eloquent exposure (1851) of the horrors of
the Neapolitan dungeons by Gladstone, who emphasized
especially the case of Pöriö, awakened the universal indignation
of Europe, but he did not obtain his liberty till 1858. He and
other exiles were then placed on board a ship bound for the
United States, but the son of Settembrini, another of the exiles, who
was on board in disguise, compelled the crew to land them at Cork,
whence Pöriö made his way to London. In the following year
he returned to Italy, and in 1860 he was elected deputy to the
parliament of Turin, of which he was chosen vice-president in
1861. He died at Florence on the 28th of April 1867.

**POETRY.** In modern criticism the word poetry (i.e. the art
of the poet, Gr. ποίησις, maker, from ποιέω, to make) is used
sometimes to denote any expression (artistic or other) of
imaginative feeling, sometimes to designate a precise literary art,
which ranks as one of the fine arts. As an expression of
imaginative feeling, as the movement of an energy, as one of those
great primal human forces which go to the development of the
race, poetry in the wide sense has played an important part as such.
In its literatures (such as that of England) poetic energy and in
others (such as that of Rome) poetic art is the
dominant quality. It is the same with individual writers. In
classical literature Pindar may perhaps be taken as a type of
the poets of energy; Virgil of the poets of art. With all his
wealth of poetic art Pindar's mastery over symmetrical methods
ever taught him to "sow with the hand," as Corinna declared,
while his poetic energy always impelled him to "sow with the
whole sack." In English poetic literature Elizabeth Barrett
Browning typifies, perhaps, the poets of energy; while Keats
(notwithstanding all his unquestionable inspiration) is mostly
taken as a type of the poets of art. In French literature Hugo,
notwithstanding all his mastery over poetic methods, represents
the poets of energy.

In some writers, and these the very greatest—in Homer,
Aeschylus, Sophocles, Dante, Shakespeare, Milton, and perhaps
Goethe—poetic energy and poetic art are seen in something like
equipoise. It is of poetry as an art, however, that we have
mainly to speak here; and all we have to say upon poetry as an
energy is that the critic who, like Aristotle, takes this wide view of
poetry—the critic who, like him, recognizes the importance of
poetry in its relations to man's other expressions of spiritual
force, claims a place in point of true critical sagacity above that
of a critic who, like Plato, fails to recognize that importance.
And assuredly no philosophy of history can be other than inadequately should it ignore the fact that poetry has had as much
effect upon human destiny as that other great human energy by
aid of which, from the discovery of the use of fire to that of the
electric light, the useful arts have been developed.

With regard to poetry as an art, most of the great poems of
the world are dealt with elsewhere in this work, either in connexion
with the names of the writers or with the various literatures to
which they belong; consequently these remarks must be confined
to general principles. Under Vézzi the detailed questions of
prosody are considered; here we are concerned with the essential
principles which underlie the meaning of poetry as such.

All that can be attempted is to inquire: (1) What is poetry? (2)
Is the position it takes up in relation to the other arts? (3)
What is its value and degree of expressive power in relation
to these? and, finally, (4) What varieties of poetic art are
the outcome of the two great kinds of poetic impulse, dramatic
imagination and lyric or egotistic imagination?

1. **What is Poetry?**—Definitions are for the most part alike
unsatisfactory and treacherous; but definitions of poetry are
proverbially so. Is it possible to lay down invariable principles
of poetry, such as those famous "invariable principles" of
William Lisle Bowles, which in the earlier part of the century
awoke the admiration of Southey and the wrath
of Byron? Is it possible for a critic to say of any
metrical phrase, stanza or verse, "This is poetry," or "This is
not poetry"? Can he, with anything like the authority with
which the man of science pronounces upon the natural objects
brought before him, pronounce upon the qualities of a poem?

These are questions that have engaged the attention of critics
ever since the time of Aristotle. Byron, in his rough and
ready way, answered them in one of those letters to his
publisher John Murray, which, rich as they are in nonsense, are
almost as rich in sense. "So far are principles of poetry from
being invariable," says he, "that they never were nor ever will be
settled. These principles mean nothing more than the
predilections of a particular age, and every age has its own and a
different from its predecessor. It is now Homer and now Virgil;
Once Dryden and since Sir Walter Scott; now Cornelle and now
Racine; now Crébillon and now Voltaire." This is putting the
case very strongly—perhaps too strongly. But if we remember
that Sophocles lost the first prize for the *Oedipus tyrannus*; if
we remember what in Dante's time (owing partly, no doubt, to the
universal ignorance of Greek) were the relative positions of
Homer and Virgil, what in the time of Milton were the relative
positions of Milton himself, of Shakespeare, and of Beaumont
and Fletcher; again, if we remember Jeffreys's famous classification
of the poets of his day, we shall be driven to pause over Byron's
words before dismissing them. Yet some definition, for the
purpose of this essay, must be here attempted; and, using
the phrase "absolute poetry" as the musical critics use the
phrase "absolute music," we may, perhaps, without too great
presumption submit the following—

**Absolute poetry is the concrete and artistic expression of the human
mind in emotional and rhythmical language.**

This at least will be granted, that no literary expression can,
properly speaking, be called poetry that is not in a certain deep
sense emotional, whatever may be its subject-matter, concrete
in its method and its diction, rhythmical in movement, and
artistic in form.

That the expression of all real poetry must be concrete in
method and diction is obvious, and yet this dictum would exclude
from the definition much of what is called didactic poetry. With
abstractions the poet has nothing to do, save to take them and
turn them into concretions; for, as artist, he is simply the man
who by instinct embodies in concrete forms that "universal
idea" which Gravina speaks of—that which is essential and
elemental in nature and in man; as poetic artist he is simply
the man who by instinct chooses for his concrete forms metrical
language. And the questions to be asked concerning any work
of art are simply these—Is that which is here embodied really
permanent, universal and elemental? and, Is the concrete form
embodying it really beautiful—acknowledged as beautiful by
the soul of man in its highest moods? Any other question is an
impertinence.

As an example of the absence of concrete form in verse take
the following lines from George Eliot's *Spanish Gypsy*—

"Speech is but broken light upon the depth
Of the unspoken; even your loved words
Float in the larger meaning of your voice
As something dimmer."

Without discussing the question of blank verse cadence and the
weakness of a line where the main accent falls upon a positive
 hiatus, "of the unspoken," we would point out that this powerful
passage is a species of prose poetry, in the abstract form. The
abstract method is substituted for the concrete. Such
an abstract phrase as "the unspoken" belongs entirely to
prose.

As to what is called ratiocinative poetry, it might perhaps be
shown that it does not exist at all. Not by syllogism, but *per
salutum*, must the poet reach in every case his conclusions. We
listen to the poet—we allow him to address us in rhythm or in
rhyme—we allow him to sing to us while other men are only
allowed to talk, not because he argues more logically than they, but because he feels more deeply and perhaps more truly. It is for his listeners to be knowing and ratiocinative; it is for him to be gnomic and divinitative.

This is perhaps the mere metrical or even rhythmical in movement, however, is what some have denied. Here we touch at once the very root of the subject. The difference between all literature and mere "word-kneading" is that, while literature is alive, word-kneading is without life. This literary life, while it is only bipartite in prose, seems to be tripartite in poetry; that is to say, while prose requires intellectual life and emotional life, poetry seems to require not only intellectual life and emotional life but rhythmic life, this last being the most important of all according to many critics, though Aristotle is not among these. Here indeed is the "fork" between the old critics and the new.

Unless the rhythm of any metrical passage is so vigorous, so natural, and so free that it seems as though it could live, if need were, by its rhythm alone, has that passage any right to exist? and should it not, if the substance is good, be forthwith demetri
cized and turned into prose? Thoreau has affirmed that prose, at its best, has high qualities of its own beyond the ken of poetry, to compensate for the sacrifice of these, should not the metrical gains of any passage be beyond all cavil?

This argument might be pressed farther still. It might seem bold to assert that, in many cases, the mental value of poetry may be questioned on the ground that the form is not an end in itself, but only a means: is it not true? The mental value of poetry must be judged by a standard not applicable to prose; but, even with regard to the different kinds of poetry, we must not compare poetry whose mental value consists of intellectual ends, logical ends, with poetry whose mental value consists partly in the suggestive richness of passion or symbol latent in rhythm (such as that of Sophocles sometimes, Pindar often, Shelley always), or latent in colour, such as that of certain of the Persian poets. To discuss the question, Which of these two kinds of poetry is the more precious? would be like admitting to our drive to admit that certain poems whose strength is rhythm, and certain other poems whose strength is colour, while devoid of any logical statement of thought, may be as fruitful of thoughts and emotions to the mind as fruits are to the body.

The mental forces at work in the production of a poem like the Excursion are of a very different kind from the mental forces at work in the production of a poem like Shelley's "Ode to the West Wind." In the one case the poet's artistic methods, like those of the Greek architect, show, and are intended to show, the solid strength of the structure. In the other, the poet's artistic methods are unlike those of the Arab architect, contradicts the idea of solid strength—make the structure to break, leave the heads like the cloud pageantry of heaven. But, in both cases, the solid strength is, and must be, there, at the base. Before the poet, therefore, you should ask himself which of these artistic methods is natural to him; he should think habitually whether instinct should be left to the weighty Romantic movement whose primary function is to state, or towards those lighter movements which we still call, for want of more convenient words, anaesthetic and dactylic, whose primary function is to suggest. Whenever Wordsworth and Keats pass from the former to the latter they pass at once into doggerel. Nor is it difficult to see why English anaesthetic and dactylic verse must suggest, and not state, as even so comparatively successful a tour de force as Shelley's "Sensitive Plant" shows. Conciseness is a primary virtue of all statement. The moment the English poet tries to "pack" his anaesthetic or dactylic line, his poetic line, like the poetic line of any nation, becomes rugged, harsh, pebbly—becomes so of necessity. Nor is this all: anaesthetic and dactylic verse must in English be essentially alliterative, or the same pebbly effect begins to be felt. The anaesthetic line is so full of syllables that in a language where the consonants dominate the vowels (as in English), these syllables grate against each other, unless their corners are artfully bevelled by one of the clauses. The anaesthetic command of an English verseform—"obtrusive alliteration, or an obtrusive alliteration of liquid sounds of form may be turned by the perfect artist to good account if his appeal to the listener's soul is primarily that of suggestion. Thenceforward the English word (Argyll's ii, 207) that "metre is the first and only condition absolutely demanded by poetry, yea even more necessary than a figurative picturesque diction." At all events this at least may be said, that the division between poetical critics is not now between Aristotelians and Baconians; it is of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the name signifies," and that "he who cannot make,

whether it be an ode by Keats or a tragedy by Sophocles, it is equally a work of art. The artist's command over form may be shown in the peasant girl's power of spontaneously rendering in simple verse, in her stornello or rispetto, thoughts through nature's symbols, it may be shown by Keats in that perfect fusion of all poetic elements of which he was such a master, in the manipulation of language so beautiful both for form and colour that thought and words seem but one blended loveliness; or it may be shown by Sophocles in a mastery over what in painting is called composition, in the exercise of that wise vision of the artist which, looking before and after, sees the thing of beauty as a whole, and enables him to grasp the eternal laws of cause and effect in art and bend them to his own wide will. In every case, indeed, form is an essential part of poetry; and, although George Sand's saying that "L'art est une forme" applies perhaps more strictly to the plastic arts (where the soul is reached partly through mechanical means), its application to poetry can hardly be exaggerated.

Owing, however, to the fact that the word poesy (first used to designate the poetic artist by Herodotus) means maker, Aristotle seems to have assumed that the indispensable basis of poetry is invention. He appears to have thought that a poet is a more on account of the composition of the action than on account of the composition of his verses. Indeed he said as much as this. Of epic poetry he declared emphatically that it produces its imitations either by pure articulate words or by metre superadded. This is to widen the definition of poetry so as to include all imaginative literature, and Plato seems to have given an equally wide meaning to the word poesia. Only while Aristotle considered poesy to be an imitation of the facts of nature, Plato considered it to be an imitation of the dreams of man. Aristotle ignored, and Plato slighted, the importance of versification (though Plato on one occasion admitted that he did not know rhythm could be called neither musician nor poet).

Perhaps the first critic who tacitly revolted against the dictum that substance, and not form, is the indispensable basis of poetry was Dionysius of Halicarnassus, whose treatise upon the arrangement of words is really a very fine piece of literary criticism. In his acute remarks upon the arrangement of the words in the sixteenth book of the Odyssey, as compared with that in the story of Gyges by Herodotus, was perhaps first enunciated clearly the doctrine that poetry is fundamentally a matter of style. The Aristotelian theory as to invention, however, dominated all criticism after as well as before Dionysius. When Bacon came to discuss the subject (and afterwards) the only division between the poetical critics was perhaps between the followers of Aristotle and those of Plato as to what poetry should, and what it should not, imitate. It is curious to speculate as to what would have been the result had the poets followed the critics in this matter. Had not the instinct of the poet been too strong for the schools, would poetry as an art have been lost and merged in such imaginative prose as Plato's? Or is not the instinct for form too strong to be stifled? By the poets themselves metre was always considered to be the one indispensable requisite of a poem, though, as regards criticism, even in the time of the appearance of the Waterley Novels, the Quarterly Review would sometimes speak of them as "poems;" and perhaps even later the same might be said of romances so concrete in method and diction, and so full of poetic energy, as Wuthering Heights and Jane Eyre, where we get absolutely all that Aristotle requires for a poem. On the whole, however, the theory that versification is not an indis
cesible requisite of a poem seems to have become nearly obsolete. Perhaps, indeed, many critics would now go so far in the way of directness through nature's symbols, it may be that metre is the first and only condition absolutely demanded by poetry, yea even more necessary than a figurative picturesque diction. At all events this at least may be said, that the division between poetical critics is not now between Aristotelians and Baconians; it is of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the name signifies," and that "he who cannot make,
that is, invent, has his name for nothing," another group contended that it is not the invention but the artistic treatment, the form, which determines whether an imaginative writer is a poet or a writer of prose. And in short, that emotion is the basis of all true poetic expression, whatever is the subject matter, that thoughts must be expressed in an emotional manner before they can be brought into poetry, and that this emotive expression demands even yet something else, viz. style and form.

Although many critics are now agreed that "L'art est une forme," that without metre and without form there can be no poetry, there are few who would contend that poetry can exist by virtue of any one of these alone, or even by virtue of all these combined. Quite independent of verbal melody, though mostly accompanying it, and quite independent of the atmosphere floating around the poet through which he sees everything, an atmosphere which stamps his utterances as poetry; for instance, among all the versifiers contemporary with Donne there was none so rugged as he occasionally was, and yet such songs as "Sweetest love, I do not go for weariness of thee" prove how true a poet he was whenever he could master those technicalities which far inferior poets find comparatively easy. While rhythm may to a very considerable degree be acquired (though, of course, the highest rhythmical effects never can), the power of looking at the world through the atmosphere that floats before the poet's eyes is not to be learned and not to be taught. This atmosphere is what we call poetic imagination. But first it seems necessary to say a word or two upon that high temper of the soul which in truly great poetry gives birth to this poetic imagination.

The "message" of poetry must be more unequivocal, more thoroughly accentuated, than that of any of the other fine arts. With regard to modern poetry, indeed, it may almost be said that if any writer's verse embodies a message, true, direct and pathetic, we cannot stay to inquire too curiously about the degree of artistic perfection with which it is delivered, for Wordsworth's saying "That which comes from the heart goes to the heart," applies very closely indeed to modern poetry. The most truly passionate poet in Greece was no doubt in a deep sense the most artistic poet; but in her case art and passion were one, and that is why she has been so cruelly misunderstood. The most truly passionate nature, and perhaps the greatest soul, that in recent years has expressed itself in English verse is Elizabeth Barrett Browning; at least it is certain that, with the single exception of Hood in the "Song of the Shirt," no writer of the 19th century really touched English hearts with a hand so powerful as hers—and this notwithstanding violations of poetic form, or defective rhymes, such as would appal some of the contemporary versifiers of England and France, who lost in numbers for the sake of a musical line. The truth is that in order to produce poetry the soul must for the time being have reached that state of exaltation, that state of freedom from self-consciousness, depicted in the lines:

"I started once, or seemed to start, in pain,
Resolved on noble things, and strove to speak,
As when a great thought strikes along the brain,
And flushes all the cheek."

Whatsoever may be the poet's "knowledge of his art," into this mood he must always pass before he can write a truly poetic line. For, notwithstanding all that may be said upon poetry as a fine art, it is in the deepest sense of the word an "inspiration." No man can write a line of genuine poetry without having been "born again" (or, as the true rendering of the text says, "born from above"); and then the mastery over those highest reaches of form which are beyond the ken of the mere versifier comes to him as a result of the change. Hence, with all Mrs Browning's metrical blemishes, the splendour of her metrical triumphs at her best.

For what is the deep distinction between poet and proseman? A writer may be many things besides a poet; he may be a warrior like Aeschylus, a man of business like Shakespeare, a courtier like Chaucer, or a cosmopolitan philosopher like Goethe; but the moment the poetic mood is upon him all the trappings of the world with which for years he may perhaps have been clothing his soul—the world's knowings, its cynicism, its self-seeking, its ambition—fall away, and the man becomes an inspired child again, with ears attuned to nothing but the whispers of those spirits from the Golden Age, who, according to Hesiod, haunt and bless the degenerate earth. What such a man produces may greatly delight and astonish his readers, yet not so greatly as it delights and astonishes himself. His passages of pathos draw no tears so deep or so sweet as those that fall from his own eyes while he writes; his sublime passages overawe no soul so imperiously as his own; his humour draws no laughter so rich or so deep as that stirred within his own breast.

It might almost be said, indeed, that Sincerity and Conscience, the two things that bring to the poet the wonders of the poetic dream, bring him also the deepest, truest delight of form. It might almost be said that by aid of sincerity and conscience the poet is enabled to see more clearly than other men the eternal limits of his own art—to see with Sophocles that nothing, not even poetry itself, is of any worth to man, invested as he is by the whole army of evil, unless it is in the deepest and highest sense good, unless it comes linking us all together by closer bonds of sympathy and pity, strengthening us to fight the foes with whom fate and even Nature, the mother who bore us, sometimes seem in league—to see with Milton that the high quality of man's soul emerges expressed by the word virtue is greater than even the great poet he prized, greater than all the rhythms of all the tongues that have been spoken since Babel—and to see with Shakespeare and with Shelley that the high passion which in English is called love is lovelier than all art, lovelier than all the marble Mercuries that "await the chisel of the sculptor" in all the marble hills.

2. What Position does Poetry take up in Relation to the other Arts?—Notwithstanding the labours of Lessing and his followers, the position accorded by criticism to poetry in relation to the other arts has never been so uncertain and anomalous as in recent years. On the one hand there are critics who, judging from their perpetual comparison of poems to pictures, claim her as a sort of handmaid of painting and sculpture. On the other hand the disciples of Wagner, while professing to do homage to poetry, have claimed her as the handmaid of music. With regard to the relations of poetry to painting and sculpture, it seems necessary to glance for a moment at the saying of Simonides, as recorded by Plutarch, that poetry is a speaking picture and that painting is a mute poetry. It appears to have had upon modern criticism as much influence since the publication of Lessing's Laocoon as it had before. Perhaps it is somewhere mentioned by Lessing that the word-painting of Homer was so full and of excessive word-painting. Beyond this one saying, there is little or nothing in Greek literature to show that the Greeks recognized between poetry and the plastic and pictorial arts an affinity closer than that which exists between poetry and music and dancing. Understanding artistic methods more profoundly than the moderns, and far too profoundly to suppose that there is any special and peculiar affinity between an art whose medium of expression is marble and an art whose medium of expression is a growth of oral symbols, the Greeks seem to have studied poetry not so much in its relation to painting and sculpture as in its relation to music and dancing. It is matter of familiar knowledge, for instance, that at the Dionysian festival it was to the poet as "teacher of the chorus" (χορηγός ή σύντροφός) that the prize was awarded, even though the "teacher of the chorus" were Aeschylus himself or Sophocles. And this recognition of the relation of poetry to music is perhaps one of the many causes of the superiority of Greek to all other poetry in adapting artistic means to artistic ends. In Greek poetry, even in Homer's description of the shield of Achilles, even in the famous description by Sophocles of his native woods in the Oedipus coloneus, such word-painting as occurs seems, if not inevitable and unconscious, so alive with imaginative feeling as to become part and parcel of the
dramatic or lyric movement itself. And whenever description is so introduced the reader of Greek poetry need not be told that the scenery itself rises before the listener's imagination which is not as vivid or outlined as a view of objects such as no amount of detailed word painting in the modern fashion can achieve. The picture even in the glorious verses at the end of the eighth book of the Iliad rises before our eyes—seems actually to act upon our bodily senses—simply because the poet's eagerness to use the picture for merely illustrating the solemnity and importance of his story lends to the picture that very authenticity which the work of the modern word-painter lacks.

That the true place of poetry lies between music on the one hand and prose, or loosened speech, on the other, was, we say, taken for granted by the one people in whom the artistic instinct was fully developed. No doubt they used the word music in a very wide sense, in a sense that might include several arts. But it is a suggestive fact that, in the Greek language, long before poetic art was called "making" it was called "singing." The poet was not σοφής but δοῦλος. And as regards the Romans it is curious to see how every now and then the old idea that poetry is singing rather than making will disclose itself. It will be remembered for instance how Terence, in the prologue of Phormio, alludes to poets as musicians. That the ancients were right in this could well be shown by a history of poetry: music and the lyrical function of the poet began together, but here, as in other things, the progress of art from the implicit to the explicit had to be delayed by each. Every art has its special function, has a certain work which it can do better than any of its sister arts. Hence its right of existence. For instance, before the "sea of emotion" within the soul has become "curdled into thoughts," it can be expressed in inarticulate tone. Hence, among the fine arts, music is specially adapted for rendering it.

It was perhaps a perception of this fact which made the Syrian Gnostics define life to be "moving music." When this sea of emotion has "curdled into thoughts," articulate language rhythmically arranged—words steeped in music and colour, but at the same time embodying ideas—can do what no mere wordless music is able to achieve in giving it expression, just as unrhymed language, language mortised in a foundation of logic, is to say prose, can best express these ideas as soon as they have cooled and settled and cleared themselves of emotion altogether. Yet every art can in some degree invade the domain of her sisters, and the nearer these sisters stand to each other the more easily and completely can this invasion be accomplished. Prose, for instance, can sometimes, as in the case of Plato, do some of the work of poetry (however imperfectly, and however tramelled by habitual conditions); and sometimes poetry, as in Pindar's odes and the waves of the Greek chorus, can do, though in the same imperfect way, the work of music.

The poems of Sappho, however, are a good case in point. Here the poet's passion is expressed so completely by the mere sound of her verses that a good recitation of them to a person ignorant of Greek would convey something of that passion to the listener; and similar examples almost as felicitous might be culled from Homer, from Aeschylus and from Sophocles. Nor is this power confined to the Greek poets. The students of Virgil have often and with justice commented on such lines as Aen. v. 481 (where the music is expressed in oxymoron, by means of rhythm), and such lines as Georg. ii. 441, where, by means of verbal effects, the gusts of wind about a tree are rendered as completely as though the voice were that of the wind itself. In the case of Sappho the effect is produced by the intensity of her passion, in the case of Homer by the intensity of the dramatic vision, in the case of Virgil by a supreme poetical art. But it can also be produced by the mere ingenuity of the artist, as in Edgar Poe's "Ulalume." The poet's object is to produce "a sense of terror, to express helpless gloom in the same way that the mere musician would have expressed it—that is to say, by monotonous recitations, by hollow and dreadful reverberations of gloomy sounds—though as matters are put when the melody was in its infancy, it only served to add gloomy ideas, in order to give to his work the intellectual coherence necessary for its existence as a poem. He even, in fact, intends us to do this, and he did it, and Ulalume properly intended was produced like the same effect upon a listener knowing no word of English that it produces upon us.

On the other hand, music can trench very far upon the domain of articulate speech, as we perceive in the wonderful instrumentation of Wagner. Yet, while it can be shown that the place of poetry is scarcely so close to sculpture and painting as to music on the one side and loosened speech on the other, the affinity of poetry to music must not be exaggerated. We must be cautious how we follow the canons of Wagner and the more enthusiastic of his disciples, who almost seem to think that inarticulate tone can not only suggest ideas but express them—can give voice to the Verstand, in short, as well as to the Verunsicht of man. Even the Greeks drew a fundamental distinction between melic poetry (poetry written to be sung) and poetry that was written to be recited. It is a pity that, while modern critics of poetry have understood, or at least have given attention to painting and sculpture, so few have possessed any knowledge of music—a fact which makes Dante's treatise De vulgari eloquio so important. Dante was a musician, and seems to have had a considerable knowledge of the relations between musical and metrical laws. But he did not, we think, assume that these laws are identical.

If it is indeed possible to establish the identity of musical and metrical laws, it can only be done by a purely scientific investigation; it can only be done by a most searching inquiry into the subtle relations that we know must exist throughout the universe between all the laws of undulation. And it is curious to remember that some of the greatest masters of verbal melody have had no knowledge of music, while some have not even shown any love of it. All Greek boys were taught music, but whether Pindar's unusual musical skill was born of natural instinct and inevitable passion, or came from the accidental circumstance that his father was, as has been alleged, a musician, and that he was as a boy elaborately taught musical science by Lasus of Hermione, we have no means of knowing. Nor can we now learn how much of Milton's musical knowledge resulted from a like exceptional "environment," or from the fact that his father was a musician. But when we find that Shelley seems to have been without the real passion for music, that Rossetti disliked it, and that Coleridge's apprehension of musical effects was of the ordinary nebulous kind, we must hesitate before accepting the theory of Wagner.

The question cannot be pursued here; but if it should on inquiry be found that, although poetry is more closely related to music than to any of the other arts, yet the power over verbal melody at its very highest is so all-sufficing to its possessor, as in the case of Shelley and Coleridge, that absolute music becomes a superfluity, this would only be another illustration of that intense egoism and concentration of force—the impulse of all high artistic energy—which is required in order to achieve the most miracles of art.

With regard to the relation of poetry to prose, Coleridge once asserted in conversation that the real antithesis of poetry was not prose but science. If he was right the difference in kind lies, not between the poet and the prose writer, but between the literary artist (the man whose instinct is to manipulate language) and the man of facts and of action whose instinct impels him to act, or, if not to act, to inquire. One thing is at least certain, that prose, however fervid and emotional it may become, must always be directed, or seem to be directed, by the reins of logic. Or, to vary the metaphor, like a captive balloon it can never really leave the earth.

Indeed, with the literature of knowledge as opposed to the literature of power poetry has nothing to do. Facts have no place in poetry until they are brought into relation with the human soul. But a mere catalogue of ships may become poetical if it tends to show the strength and pride and glory of the warriors who manned them; as for instance Troy; a detailed description of the designs upon a shield, however beautiful and poetical in itself, becomes still more so if it tends to show the skill of the divine artificer and the invincible splendour of a hero like Achilles. But mere dry exactitude of imitation is not for poetry but for loosened speech. Hence, most of the so-called poetry of Hesiod is not poetry at all. The Muses who spoke to him about "truth" on Mt Helicon made the common mistake of confounding fact with
Now quite Manu's Counterpoint, This familiar melodious departed we the after now Shakespeare, Strophe endeavours great art. Plato sufficient based nistic, of ture, is the poet bois, " Victor of Homer, prose. master is he who makes music, and loses the least that can be lost from metre, so with regard to the relations between poetry and prose the greatest master is he who borrows the most that can be borrowed from prose and loses the least that can be lost from verse. No doubt this is what every poet tries to do by instinct; but some sacrifice on either side there must be, and, with regard to poetry and prose, modern poets at least might be divided into those who make picturesqueness yield to verbal melody, and those who make verbal melody yield to picturesqueness.

With the close of the eighteenth century as perhaps the melodist, it is made subservient to outline or to colour; with the other class colour and outline both yield to metre. The chief aim of the first class is to paint a picture; the chief aim of the latter is to paint itself. Weber, in driving through a beautiful country, could only enjoy its beauty by translating it into music. The same may be said of some poets with regard to verbal melody. The supreme artist, however, is he whose pictorial and musical power are so interfused that each seems born of the other, as is the case with Sappho, Homer, Aeschylus, Sophocles, and indeed most of the great Greek poets. Among English poets (leaving the two supreme masters unconsidered, and only doubting if the nation born colour seems born of the music and the music born of the colour. In French poetry the same triumph has been achieved in Victor Hugo's magnificent poem "En marchant la nuit dans un bous," which, as a rendering through verbal music of the witchery of nature, stands alone in the poetry of France. For there the poet conquers that crowning difficulty we have been alluding to, the difficulty of stealing from prose as much distinctness of colour and clearness of outline as can be imported into verse with as little sacrifice as possible of melody.

If poetry can in some degree invade the domain of prose, so on the other hand prose can at times invade the domain of poetry, and no doubt the prob of Plato—what is called poetical prose—is a legitimate form of art. Poetry, the earliest form of literature, is also the final and ideal form of all pure literature; and, when Landor insists that poetry and poetical prose are antagonistic, we must remember that Landor’s judgments are mostly based on feeling, and that his hatred of Plato would be quite sufficient basis with him for an entire system of criticism upon poetical prose. As with Carlyle, there was a time in his life when Plato had serious thoughts of becoming a poet. And perhaps, like Carlyle, having the good sense to see his true function, he himself desisted from writing, and strictly forbade other men to write, in verse. If we consider this, and if we consider that certain of the great English masters of poetical prose of the 17th century were as incapable of writing in metre as their followers Richter and Carlyle, we shall hardly escape the conclusion on the one hand that the faculty of writing poetry is quite another faculty than that of producing work in the arts most closely allied to it, music and prose, but that on the other hand there is nothing antagonistic between the two faculties.

Value in Expressional Power.—There is one great point of superiority that musical art exhibits over metrical art. This consists, not in the capacity for melody, but in the capacity for harmony in the musician’s sense. The finest music of Aeschylus, of Pindar, of Shakespeare, of Milton, is after all only a succession of melodious notes, and, in endeavouring to catch the harmonic intent of strophe, antistrope and epode in the Greek chorus and in the true ode (that of Pindar), we can only succeed by pressing memory into our service. We have to recall by memory the waves that have gone before, and then to imagine their harmonic power in relation to the present and the future. But the musical art is present occupying the ear. Counterpoint, therefore, is not to be achieved by the metricist, even though he be Pindar himself; but in music this perfect ideal harmony was fore-shadowed perhaps in the earliest writing. We know at least that as early as the 12th century counterpoint began to show a vigorous life, and the study of it is now a familiar branch of musical science. Now, inasmuch as “nature’s own hymn” is and must be the harmonic blending of apparently independent and apparently discordant notes, among the arts whose appeal is through the ear that which can achieve counterpoint must perhaps rank as a pure art above one which cannot achieve it. We are of course speaking here of metre only. We have not space to inquire whether the counterpoint of absolute poetry is the harmony underlying the appeal of the musical art,—the emotion produced by a word being more persistent than the emotion produced by an inarticulate sound. But if poetry falls behind music in rhythmic scope, it is capable of rendering emotion after emotion has become disintegrated into thoughts, and here, as we have seen, it enters into direct competition with the art of prose. It can use the emphasis of sound, not for its own sake merely, but to strengthen the emphasis of sense, and can thus give a fuller and more adequate expression to the soul of man than music at its highest can give.

With regard to prose, no doubt such writings as Plato’s description of the chariot of the soul, his description of the island of Atlantis, or of E’t’s visit to the place of departed souls, comes but a short way behind poetry in imaginative and even rhythmic appeal. It is impossible, however, here to do more than touch upon the subject of the rhythm of prose in its relation to the rhythm of poetry; for in this matter the genius of each individual language has to be taken into account.

Perhaps it may be said that deeper than all the rhythm of art is that rhythm which art would fain catch, the rhythm of nature; for the rhythm of nature is the rhythm of life itself. This rhythm can be caught by prose as well as by poetry, such prose, for instance, as that of the English Bible. Certainly the rhythm of verse at its highest, such, for instance, as that of Shakespeare’s greatest writings, is nothing more and nothing less than the metre of that energy of the spirit which surges within the bosom of him who speaks, whether he speak in verse or in impassioned prose. Being rhythm, it is of course governed by law, but it is a law which transcends in subtlety the conscious art of the metricist and is only caught by the poet in his most inspired moods, a law which, being part of nature’s own sanctions, can of course never be formulated but only expressed, as it is expressed in the melody of the bird, in the incoparable harmony of the entire bird-chorus of a thicket, in the whisper of the leaves of the tree, and in the song or wall of wind and sea. Now it is not this rhythm of nature represented by that “sense rhythm” which prose can catch as well as poetry, that sense rhythm whose finest expressions are to be found in the Bible, Hebrew and English, and in the biblical movements of the English Prayer Book, and in the dramatic prose of Shakespeare at its best? Whether it is caught by prose or by verse, one of the virtues of the rhythm of nature is that it is translatable. Hamlet’s profession about man and Raleigh’s apostrophe to death are as translatable into other languages as are the Hebrew psalms, or as is Manu’s magnificent passage about the singleness of man. "Single is each man born into the world; single he dies; single he receives the reward of his good deeds, and single the punishment of his evil deeds. When he dies his body lies like a fallen tree upon the earth, but his virtue accompanies his soul. Wherefore let man have his own garner with which he may be content in traversing that gloom which is so hard to be traversed."

Here the rhythm, being the inevitable movement of emotion and "sense," can be caught and translated by every literature under the sun. While, however, the great goal before the poet is to compel the listener to expect his caesural effects, the great goal before the writer of poetical prose is in the very opposite direction; it is to make use of the concrete figures and impassioned
diction of the poet, but at the same time to avoid the recognized and expected metrical bars upon which the poet depends. The moment the prose poet passes from the rhythm of prose to the rhythm of metre the apparent sincerity of his writing is destroyed.

As compared with sculpture and painting the great infinitry of poetry, as an "imitation" of nature, is of course that the medium is always the same, and to write no words could, in the dramatic situation, have been spoken. It is not only Homer who is obliged sometimes to forget that passion when at white heat is never vulnerable, is scarcely even articulate; the dramatists also are obliged to forget that in love and in hate, at their tensest, words seem weak and foolish when compared with the silent and satisfying triumph and glory of deeds, such as the plastic arts can render. This becomes manifest enough when we compare the Niobe group or the Laocoon group, or the great dramatic paintings of the modern world, with even the finest efforts of dramatic poetry, such as the speech of Andromache to Hector, or the speech of Priam to Achilles, nay such as even the cries of Cassandra in the Agamemnon, or the wranglings of Lear over the dead Cordelia. Even when writing the words uttered by Oedipus, as the terrible truth breaks upon his soul, Sophocles must have felt that in the holiest chambers of sorrow and in the highest agonies of suffering reigns that awful silence which not poetry, but painting sometimes, and sculpture always, can render. What human sounds could render the agony of Niobe, or the agony of Laocoon, as we see them in the sculptor's rendering? Not articulate speech at all; not words but wails. It is the same with hate; it is the same with love. We are not speaking merely of the unpacking of the heart in which the angry warriors of the Iliad indulge. Even such subtle writing as that of Aeschylus and Sophocles falls below the work of the painter. Hate, though voluble perhaps, as Clytemnestra's when hate is at that red-heat glow which the poet can render, changes in a moment whenever that redness has been fanned to hatred's own last complication—whiteness as of iron at the melting-point—when the heart has grown far too big to be "unpacked" at all, and even the bitter epigrams of hate's own rhetoric, though brief as the terrier's snap before he fleshes his teeth, or as the short snarl of the tigress as she springs before her cubs in danger, are all too slow and sluggish for a soul to which language at its tensest has become idle play. But this is just what a poet cannot render by an art whose medium consists solely of words.

It is in giving voice, not to emotion at its tensest, but to the variations of emotion, it is in expressing the countless shifting movements of the soul from passion to passion, that poetry shows in spite of all her infirmities her superiority to the plastic arts. Hamlet and the Agamemnon, the Iliad and the Oedipus Tyrannus, are adequate to the entire breadth and depth of man's soul.

Varieties of Poetic Art.—We have now reached the inquiry: What varieties of poetic art are the outcome of the two kinds of poetic impulse, dramatic imagination and lyric or egotistic imagination? It would be impossible here to examine fully the subject of poetic imagination. In order to do so we should have to enter upon the vast question of the effect of artistic environment upon the development of man's poetic imagination; we should have to inquire how the instinctive methods of each poet and of each group of poets have been modified and often governed by the methods characteristic of their own time and country. We should have to inquire, for instance, how far such landscape as that of Sophocles in the Oedipus Colonus and such landscape as that of Wordsworth depends upon difference of individual temperament, and how far upon difference of artistic environment. We might go through a similar analysis of poetic imagination, the question of artistic environment must be taken into account, the case of the Iliad is alone sufficient to show.

Ages before Phrynichus, ages before an acted drama was dreamed of, a dramatic poet of the first order arose, and, though he was obliged to express his splendid dramatic imagination through epic forms, he expressed it almost as fully as if he had inherited the method and the stage of Sophocles. And if Homer never lived at all, then an entire group of dramatic poets arose in remote times whose method was epic instead of dramatic simply because there was then no stage. This, contrasted with the fact that in a single half-century the tragic art of Greece arose with Aeschylus, culminated with Sophocles, and decayed with Euripides, and contrasted also with the fact that in England at another time, and in another word, in another environment, the whole poetic imagination of the country found expression in the acted drama alone, is sufficient to show that a poet's artistic methods are very largely influenced by the artistic environments of his country and time. So vast a subject as this, however, is beyond our scope, and we can only point to the familiar instance of the troubadours and the trouvères and then pass on.

With the trouvère (the poet of the langue d'oil), the story or situation is always the end of which the musical language is the means; with the troubadour (the poet of the langue d'oc), the form is so beloved, the musical language so enthralling, that, however beautiful may be the story or situation, it is felt to be no more than the means to a more beloved and beautiful end. But then nature makes her own troubadours and her own trouvères irrespective of fashion and of time—irrespective of langue d'oc and langue d'oil. And, in comparing the troubadours with the trouvères, this is what strikes us at once—there are certain troubadours who by temperament, by original endowment of nature, ought to have been trouvères, and there are certain trouvères who by temperament ought to have been troubadours. Surrounding conditions alone have made them what they are. There are those whose impulse (though writing in obedience to contemporary fashions) is manifestly to narrate, and there are those whose impulse (though writing in obedience to contemporary fashions fabliaux in the langue d'oil) is simply to sing. In other words, there are those who, though writing about the fashion of their brother-trouvères, are far more occupied with the life within them than with that outer life which the taste of their time and country calls upon them to paint—born egoists, who must have the freedom of the external as well as internal into verbal melody. Of the former class Pierre Vidal, of the latter class the author of Le Lay de Veiselet, may be taken as the respective types.

That the same forces are seen at work in all literatures few students of poetry will deny—though in some poetical groups these forces are no doubt more potent than in others, as, for instance, with the great parable poets of Persia, in some of whom there is perpetually apparent a conflict between the dominance of the Oriental taste for allegory and subtle suggestion, as expressed in the Zoroastrian definition of poetry—"apparent pictures of unapparent realities"—and the opposite yearning to represent human life with the freshness and natural freedom characteristic of Western poetry.

Allowing, however, for all the potency of external influences, we shall not be wrong in saying that of poetic imagination there are two distinct kinds—(1) the kind of poetic imagination seen at its highest in Aeschylus, Sophocles, Shakespeare and Homer, and (2) the kind of poetic imagination seen at its highest in Pindar, Dante and Milton, or else in Sappho, Heine and Shelley. The former, being in its highest dramatic exercise unconditioned by the personal or lyrical impulse of the poet, might perhaps be called absolute: the latter, though more or less conditioned by the personal or lyrical impulse of the poet, might be called relative dramatic vision. It seems impossible to classify poets, or to classify the different varieties of poetry, without drawing some such distinction as this, whatever words of definition we may choose to adopt.

For the achievement of all pure lyric poetry, such as the ode, the song, the elegy, the idyll, the sonnet, the stornello, it is
evident that the imaginative force we have called relative vision will suffice. And if we consider the matter thoroughly, in many other forms of poetic art—forms which at first sight might seem to require absolute vision—we shall, find nothing but relative vision at work.

Even in Dante, and even in Milton and Virgil, it might be difficult to trace the working of any other than relative vision. And as to the entire body of Asiatic poets it perhaps might be found (even in view of the Indian drama) that relative vision suffices to do all their work. Indeed the temper which produces true drama is, it might almost be said, a growth of the Western mind. For, unless it be Semitic, as seen in the dramatic narratives of the Bible, or Chinese, as seen in that remarkable prose story, The Two Fair Cousins, translated by Rémusat, absolute vision seems to have but small place in the literatures of Asia. The wonderfulness of the world and the romantic possibilities of fate, or circumstance, or chance—not the wonderfulness of the character to whom these possibilities befall—are ever present to the mind of the Asiatic poet. Even in so late a writer as the poet of the Shāh Nāmeh, the hero Irij, the hero Zal and the hero Zohreb are in character the same person, the virtuous young man who combines the courage of youth with the wisdom and forbearance of age. And, as regards the earlier poets of Asia, it was not till the shadowy demigods and heroes of the Asiatic races crossed the Caucasus, and breathed a more bracing air, that they became really individual characters. But among the many qualities of man's mind that were invigorated and rejuvenated by that great exodus from the dreamy plains of Asia, it is be counted, above all others, his poetic imagination. The mere sense of wonder, which had formerly been an all-sufficing source of pleasure to him, was all-sufficing no longer. The wonderful adventure must now be connected with a real and interesting individual character. It was left for the poets of Europe to show that, given the interesting character, given the Achilles, the Odysseus, the Helen, the Priam, any adventure happening to such a character becomes interesting.

What then is this absolute vision, this true dramatic imagination which can hardly be found in Asia—which even in Europe cannot be found except in rare cases? Between relative and absolute vision the difference seems to be that, the former only enables the poet, even in its highest exercise, to make his own individuality, or else humanity as represented by his own individuality, live in the imagined situation; the latter enables him in its highest exercise to make special individual characters other than the poet's own live in the imagined situation.

"That which exists in nature," says Hegel, "is a something purely individual and particular. Art, on the contrary, is essentially destined to manifest the general." And no doubt this is true as regards the plastic arts, and true also as regards literary art, save in the very highest reaches of pure drama and pure lyric, when it seems to become art no longer—when it seems to become the very voice of Nature herself. The cry of Priam when he puts to his lips the hand that slew his son is not merely the cry of a bereaved and aged parent; it is the cry of the individual king of Troy, and expresses above everything else that most naive, pathetic and winsome character. Put the words into the mouth of the irascible and passionate Lear and they would be entirely out of keeping.

It may be said then that, while the poet of relative vision, even in its highest exercise, can only, when depicting the external world, deal with the general, the poet of absolute vision can compete with Nature herself and deal with both general and particular. If this is really the case, we may perhaps find a basis for a classification of poetry and of poets. That all poets must be singers has already been maintained. But singers seem to be divisible into three classes: first the pure lyricists, each of whom can with his one voice sing only one tune; secondly the epic poets, save Homer, the bulk of the narrative poets, and the comic-dramatists, each of whom can with his one voice sing several tunes; and thirdly the true dramatists, who, having, like the nightingale of Gongora, many tongues, can sing all tunes.

It is to the first-named of these classes that most poets belong. With regard to the second class, there are not of course many poets left for it: the first absorbs so many. But, when we come to consider that among those who, with each his one voice, can sing many tunes, are Firdausi, Firdausi, Jami, Virgil, Dante, Milton, Spenser, Goethe, Byron, Coleridge, Shelley, Keats, Schiller, Victor Hugo, the second class is so various that no generalization save such a broad one as ours could embrace its members. And now we come to class three, and must pause. The third class is necessarily very small. In it can only be placed such names as Shakespeare, Aeschylus, Sophocles, Homer and (hardly) Chaucer.

These three kinds of poets represent three totally different kinds of poetic activity.

With regard to the first, the pure lyricists, the impulse is pure egoism. Many of them have less of even relative vision at its highest than the mass of mankind. They are not too much engaged with the emotions within to have any deep sympathy with the life around them. Of every poet of this class it may be said that his mind to him "a kingdom is," and that the smaller the poet the bigger to him is that kingdom. To make use of a homely image—like the chaffinch whose eyes have been pricked by the bird-fancier, the pure lyricist is sometimes a warbler because he is blind. Still he feels that the Muse loves him exceedingly. She takes away his eyesight, but she gives him sweet song. And his song is very sweet, very sad, and very beautiful; but it is all about the world within his own soul—its sorrows, its joys, its passions, its thoughts. To the pure lyricist the world is all within himself.

With regard to the second class the impulse here is no doubt a kind of egoism too; yet the poets of this class are all of a different temper from the pure lyricists; they have a wide imagination; but they are still relative, still egotistic. They have splendid eyes, but eyes that never get beyond seeing general, universal humanity (typified by themselves) in the imagined situation. Not even to these is it given to break through that law of centrality by which every "me" feels itself to be the central "me"—the only "me" of the universe, round which all other spurious "me's" revolve. This "me" of theirs can transmute into many shapes, but they cannot create other "me's"—nay, for egoism, some of them scarcely would, perhaps, if they could.

The third class, the true dramatists, whose impulse is the simple yearning to create akin to that which made "the great Vishnu yean to create a world," are of imagination all compact—so much so that when at work "the divinity" which Iamblichus speaks of "seizes for the time the soul and guides it as he will."

The distinction between the pure lyricists and the other two classes of poets is obvious enough. But the distinction between the quasi-dramatists and the pure dramatists requires a word of explanation before we proceed too much to touch upon the various kinds of poetry that spring from the exercise of relative and absolute vision. Sometimes, to be sure, the vision of the true dramatists—"the greatest dramatists"—will suddenly become narrowed and obscured, as in that part of the Oedipus Tyrannus where Sophocles makes Oedipus ignorant of what every one in Thebes must have known, the murder of Laius. And again, finely as Sophocles has conceived the character of Electra, he makes her, in her dispute with Chrysothemis, give expression to sentiments that, in another play of his own, come far more appropriately from the lofty character of Antigone. In a parallel dispute with Idem, and, on the other hand, examples of relative vision in its furthest reaches can be found in abundance everywhere, especially in Virgil, Dante, Calderon and Milton. Some of the most remarkable examples of that high kind of relative vision which may easily be mistaken for absolute vision may be found in those great prose epics of the North which Aristotle would have called poems. Here is one from the Volvo Söga. While the brothers of Gudrun are about their treacherous business of murdering Sigurd, his husband, as he lies asleep in her arms, Brynhild, Sigurd's former lover, who in the frenzy of
“love turned to hate” has instigated the murderers to the deed, hovers outside the chamber with Gunnar, her husband, and listens to the wail of her rival who is waltering in Sigurd’s blood. At the sound of that wail Brynhildr laughs:

“Then said Gunnar to her, Thou laughest not because thy heart roots are gladdened, or else why doth thy visage wax so wan?”. This is of course very fine; but, as any two characters in that dramatic situation might have done that dramatic business, fine as it is—as the sagaman gives us the general and not the particular—the vision at work is not absolute but relative at its very highest exercise. But our examples will be more interesting if taken from English poets. In Coleridge’s “Ancient Mariner” we find an immense amount of relative vision of so high a kind that at first it seems absolute vision. When the ancient mariner, in his narrative to the wedding guest, reaches the slaying of the albatross, he stops, he can proceed no farther, and the wedding guest exclaims:

“God save thee, Ancient Mariner, From the fends that plague thee thus! Why look’st thou so? ‘With my cross-bow I shot the albatross.”

But there are instances of relative vision—especially in the great master of absolute vision, Shakespeare—which are higher still—so high indeed that not to relegate them to absolute vision seems at first sight pedantic. Such an example is the famous speech of Lady Macbeth in the second act, where she says:

“Had he not resembled My father as he slept, I had done’t.”

Marvellously subtle as this speech, it will be found, if analysed, that it expresses the general human soul rather than any one special human soul. Indeed Leigh Hunt records the case of a bargeman who, charged with robbing a sleeping traveller in his barge, used in his confession almost identical words—“Had he not looked like my father as he slept, I should have killed as well as robbed him.” Again, the thousand and one cases (to be found in every literature) where a character, overwhelmed by some sudden surprise or terror, asks whether the action going on is that of a dream or of real life, must all, on severe analysis, be classed under relative rather than under absolute vision—even such a fine speech, for instance, as that where Pericles, on discovering Marina, exclaims:

“This is the rarest dream that e’er dull sleep Did mock sad fools withal!”

or as that in the third act of Titus Andronicus, where Titus, beholding his mutilated and ruined daughter, asks:

“When will this fearful slumber have an end?”

even here, we say, the humanity rendered is general and not particular, the vision at work is relative and not absolute. The poet, as representing the whole human race, throwing himself into the imagined situation, gives us what general humanity would have thought, felt, said or done in that situation, not what one particular individual and he alone would have thought, felt, said or done.

Now what we have called absolute vision operates in a very different way. So vividly is the poet’s mere creative instinct at work that the ego sinks into passivity—becomes insensitive to all impressions other than those dictated by the vision—by the “divinity” which has “seized the soul.” Shakespeare is full of examples. Take the scene in the first act of Hamlet where Hamlet hears for the first time, from Horatio, that his father’s ghost haunts the castle. Having by short sharp questions elicited the salient facts attending the apparition, Hamlet says: “I would I had been there.” To this Horatio makes the very commonplace reply, “It would have much amused you.” Note the marvellously dramatic reply of Hamlet—“Very like, very like! Stayed it long?” Suppose that this dialogue had been attempted by any other poet than a true dramatist, or by a true dramatist in any other mood than his very highest, Hamlet, on hearing Horatio’s commonplace remarks upon phenomena which to Hamlet were more subversive of the very order of the universe than if a dozen stars had fallen from their courses, would have burst out with: “Amazed me!” and then would have followed an eloquent declamation about the “amazing” nature of the phenomena and their effect upon him. But so entirely has the poet become Hamlet, so completely has the divinity seized his soul, that all language seems equally weak for expressing the turbulence within the soul of the character, and Hamlet exclaims in a sort of meditative irony, “Very like, very like!” It is exactly this one man Hamlet, and no other man, who in this situation would have so expressed himself. Charles Knight has some pertinent remarks upon this speech of Hamlet; yet he misses its true value, and treats it from the general rather than from the particular side. Instances of absolute vision in Shakespeare crowd upon us; but we can find room for only one other. In the pathetic speech of Othello, just before he kills himself, he declares himself to be:

“One pot easily jealous, but, being wronged, Perplexed in the extreme.”

Consider the marvellous timbre of the word “wronged,” as coming from a character like Othello. When writing this passage, especially when writing this word, the poet had become entirely the simple English soldier-hero, as the Moor really is—he had become Othello, looking upon himself “as not easily jealous,” whereas he was “wronged” and “perplexed in the extreme” by tricks which Hamlet would have seen through in a moment.

While all other forms of poetic art can be vitalized by relative vision, there are two forms (and these the greatest) in which absolute vision is demanded, viz. the drama, and in the poetic—Dramatic Imagization.

Very much of the dramatist’s work can be, and in fact is, effected by egoistic imagination, while true dramatic imagination is only called into play on comparatively rare occasions. Not only fine but sublime dramatic poems have been written, however, where the vitalizing power has been entirely that of lyrical imagination. We need only instances the Prometheus Bound of Aeschylus, the most sublime poet in the world. The drama of Shelley too, like those of Victor Hugo and Calderon, are informed entirely by egoistic imagination. In all these splendid poems the dramatist places himself in the imagined situation, or at most he places there some typical conception of universal humanity. There is not in all Calderon any such display of dramatic imagination as we get in that wonderful speech of Priam’s in the last book of the Iliad, to which we have before alluded. There is not in the Cenci such a display of dramatic imagination as we get in the sudden burst of anger from the spoilt child of gods and men, Achilles (anger which alarms the hero himself as much as it alarms Priam), when the prattle of the old man has carried him too far. It may seem bold to say that the drama of Goethe is informed by egoistic imagination only—assuredly the prison-scene in Faust is unsurpassed in the literatures of the world. Yet, perhaps, it could be shown of the passion and the pathos of Gretchen throughout the entire play that it betrays a female character general and typical rather than individual and particular.

The nature of this absolute vision or true dramatic imagination is easily seen if we compare the dramatic work of writers without absolute vision, such as Calderon, Goethe, Ben Jonson, Fletcher and others, with the dramatic work of Aeschylus and of Shakespeare. While of the former group it may be said that each poet has his imagination, the Aeschylus, and Shakespearian, must be said that each in his highest dramatic mood does not work, but is worked by his imagination. Note, for instance, how the character of Clytaemnestra grows and glows under the hand of Aeschylus. The poet of the Odyssey had distinctly said that Agisthus, her paramour, had struck the blow, but the dramatist, having imagined the greatest tragic female in all poetry, finds it impossible to let a man like Aegisthus assist such a woman in a homicide so daring and so momentous. And

Translation of Morris and Magnusson.
when in that terrible speech of hers she justifies her crime (ostensibly to the outer world, but really to her own conscience), the way in which, by the sheer magnetism of irresistible personality, she draws us to recognize her and her crime is unrivalled out of Shakespeare and not surpassed even there. In the Great Drama, in the Agamemnon, in Othello, in Hamlet, in Macbeth, there is an imagination at work whose laws are inexorable, and inevitable, as the laws by the operation of which the planets move around the sun. But in this essay our business with drama is confined entirely to its relations to epic.

Considering how large and on the whole how good is the body of modern criticism upon drama, it is surprising how poor is the modern criticism upon epic. Aristotle, comparing tragedy with epic, gives the palm to tragedy as being the more perfect art, and nothing can be more ingenious than the way in which he has marshalled his reasons. He tells us that tragedy as well as epic is capable of producing its effect even without action; we can judge of it perfectly, says he, by reading. He goes so far as to say that, even in reading as well as in representation, tragedy has an advantage over the epic, the advantage of greater clearness and distinctness of impression. And in some measure this was perhaps true of Greek tragedy, for as Müller in his Dissertations on the Eumenesides has well said, the ancients always remained and wished to remain conscious that the whole was a Dionysian entertainment; the quest of a commonplace ἀπάντησε came afterwards. And even of Romantic Drama it may be said that in the time of Shakespeare, and indeed down through the 18th century, it never lost entirely its character of a recreation as well as a drama. It was not till melodrama began to be recognized as a legitimate form of dramatic art that the dialogue had to be stricken from the dramatic action "at full speed"—struck like sparks from the roadster's shoes. The truth is, however, that it was idle for Aristotle to inquire which is the more important branch of poetry, epic or tragedy. Equally idle would it be for the modern critic to inquire how much romantic drama gained and how much it lost by abandoning the chorus.

Much has been said as to the scope and the limits of epic and dramatic poetry. If in epic the poet has the power to take the imagination of his audience away from the dramatic centre and show what is going on at the other end of the great web of the world, he can do the same thing in drama by the chorus, and also by the introduction into the dramatic circle of messengers and others from the outside world. But, as regards epic poetry, is it right that we should hear, as we sometimes do hear, the voice of the poet himself as chorus bidding us contrast the present picture with other pictures afar off, in order to enforce its teaching and illustrate its pathos? This is a favourite method with modern poets and a still more favourable one with prose narrators. Does it not give an air of self-consciousness to poetry? Does it not disturb the intensity of the poetic vision? Yet it has the sanction of Homer; and who shall dare to challenge the methods of the great father of epic? An instance occurs in IIiad v. 156, where, in the midst of all the stress of fight, the poet leaves the dramatic action to tell us what became of the inheritance of Phaeonops, after his two sons had been slain by Diomedes. Another instance occurs in iii. 243-244, where the poet, after Helen's pathetic mention of her brothers, comments on the causes of their absence, "criticizes life" in the approved modern way, generalizes upon the impotence of human intelligence—the impotence even of human love—to pierce the darkness in which the web of human fate is woven. Thus she spoke (the poet tells us); but the life-giving earth already possessed them, there in Lacedaemon, in their dear native land:—

Δε φάτον οιχήν Θην ἡλεκτή φωτίσσον αὐτ ἐν Δαλαγάμνου αὖθι, ὥροιν ὣν πατερά γαῖῃ.

This, of course, is "beautiful exceedingly," but, inasmuch as the imagination at work is egotistic or lyrical, not dramatic; inasmuch as the vision is relative, not absolute, it does not represent that epic strength at its very highest which we call specially "Homerian," unless indeed we remember that with Homer the Muses are omniscient; this certainly may give the passage a deep dramatic value it otherwise seems to lack.

The deepest of all the distinctions between dramatic and epic methods has relation, however, to the nature of the dialogue. Aristotle failed to point it out, and this is remarkable until we remember that his work is but a fragment of a great system of criticism. In epic poetry, and in all poetry that narrates, the poet be muses that the reader himself is the drama, as Gottfried von Strassburg, or Turolldus, the action, of course, moved by aid partly of narrative and partly by aid of dialogue, but in drama the dialogue has a quality of suggestiveness and subtle inference which we do not expect to find in any other poetic form save perhaps that of the purely dramatic ballad. In ancient drama this quality of suggestiveness and subtle inference is seen not only in the dialogue, but in the choral odes. The third ode of the Agamemnon is an extreme case in point, where, by a kind of double entendre, the relations of Clytaemnestra and Aegisthus are darkly alluded to under cover of allusions to Paris and Helen. Of this dramatic subtlety Sophocles is perhaps the greatest master; and certain critics have been led to speak as though irony were heart-thought of Sophoclean drama. But the suggestiveness of Sophocles is pathetic (as Professor Lewis Campbell has well pointed out), not ironical. This is one reason why drama more than epic seems to satisfy the more intellect of the reader, though this may be counterbalanced by the hardness of mechanical structure which sometimes disturbs the reader's imagination in tragedy.

When, for instance, a dramatist pays so much attention to the evolution of the plot as Sophocles does, it is inevitable that his result should be more and more a concatenation of events: if something had to happen every day and everything to happen every day, it is not to be wondered at if his characters are nothing but mere ciphers, if the Iliad alone is taken to represent Greek epic. The Greek Epic. In speaking of the effect that surrounding conditions seem to have upon the form in which the poetic energy of any time or country should express itself, we instance the Iliad as a typical case. The imagination vivifying it is primarily dramatic. The characters represent much more of the mere body of the man than of the man. Notwithstanding all the splendid works of Calderon, Marlowe, Webster and Goethe, it is doubtful whether a born dramatist the poet of the Iliad does not come nearer to Aeschylus and Shakespeare than does any other poet. His very art for making the dramatic speech is incapable of a fault in the Iliad considered as pure epic, and the unconscious way in which each actor is made to depict his own character is in the highest spirit of drama. It is owing to this peculiarity of the Iliad that it stands almost alone among all our productions of the drama, and this being the case, it is the poet's part or the epic to be created with the epic form and not with the epic of art. All epics are clearly divisible into two classes, first those which are mere accretions of poems or traditional ballads, and second, those which, though based indeed on tradition or history, have become so fused in the mind of one great poet, so strained, therefore, with the colour and temper of that mind, as to become new crystallizations—inventions, in short, as we understand that word. Each kind of epic has exercised a peculiar form of power, one peculiar and indeed necessary defects. In the one we get the freedom—apparently schemeless and motiveless—of nature, but, as a consequence, miss that hard acorn of thought (to use the Greek word) Definitive as the heart of a man) which the mind asks for as the core of every work of art. In the other this great requisite of an adequate central thought is found, but accompanied by a construction, a scheme, which has been hinted, though Nature herself is that she never ceases us with any obstructive exhibitions of scheme, she doubtless has a scheme somewhere, she does somewhere hide a "hard acorn of thought" of which the poet is bound to be clear in his own mind, and this being the case that art should have a scheme too; but in such a dilemma is she placed in this matter that the epic poet, unless he is evidently telling the
story for its own sake, scornful of purposes ethical or aesthetic, must
sacrifice illusion.

Among the former class of epics are to be placed the great epics of
growth, such as the Mahabharata, the Nibelung story, &c.; among
the latter the Odyssey, the Aeneid, Paradise Lost, the Jerusalem
Liberation, the Lusiads.

In what classification are we to find a place for the
liad? The heart-thought of the greatest epic in all literature is
simply that Achilles was vexed and that the fortunes of the
world depended upon whether or not a suit of new armor for him was
found. Notwithstanding the acute criticisms of Wollf, it remains
difficult for us to find a place for the liad among the epics of
growth. And why? Because throughout the liad the dramatic imagination shown is of the first
order. There is no need to seek in this poem for the
artistic motive the Odyssey stands alone among the epics of
art, the world, as we are going to see.

It is manifest that, as the pleasure derived from the epic of art
is that of recognizing a conscious scheme, if the epic of art fails
through confusion of scheme it fails altogether. What
is demanded of the epic of art (as some kind of compensa-
tion for that natural freedom of evolution which it
can never achieve, that sweet abandon, which belongs to nature
and to the epic of growth alike) is unity of impression, harmonious
and artistic arrangement of the different parts. And when, in
the liad, Virgil strikes the middle of his epic, he perceives
with his own thoughts and reflections on things in
general. Fine as is the speech of Anchises to Aeneas in Elysium
(Like the wind, the pensive, tendered: the secret
decree of chance, construing the map, the
poem as developed in the previous books shows how entirely Virgil lacked
that artistic power shown in the Odyssey of making a story
become the natural and inevitable outcome of an artistic idea.

In the liad there is that artistic redaction of Virgil, but
with even less attention to a central thought than Virgil exhibits.
Firdaуси relays for his effects upon the very qualities which characterize
the liad, the unity of impression, the artistic arrangement of the
epic; and he does not seek for a natural and an artificial flow of the story; so much indeed that, if the
liad and the Kalandra, he may have
aggregation of the national ballad poems and the work of a single
artificer. That Firdaуси was capable of working from a centre
not only artistic but philosophic his Vesiy aand Zewi shafts; and if we
consider the general artistic temper of Firdaуси's time, what indeed has been that temper during the whole of
the Mahomedan period, the subtle temper of the parlor poet—
the liad, with its direct appeal to popular sympathies, is a
substantial contribution to literature.

With regard, however, to Virgil's defective power of working
from an artistic motive, as compared with the poet of the
Odyssey, this is not a peculiarity but a fundamental characteristic of the
liad; it is a peculiarity which has to be stated under his name and
is by no means a peculiarity of the time. Certainly he shows it with the writer of Paradise Lost, who, setting out to
"justify the ways of God to man," forgets occasionally the
original worker of the evil, as where, for instance, he substitutes
chance as soon as he comes (at the end of the second book) to
the point upon which the entire epic movement turns, the escape of
Satam from hell and his journey to earth for the ruin of man:—

"At last his sail-broad vans
He spreads for flight, and, in the surging smoke
Upward, spares the growing mists and the many a league,
As in a cloudy chair, ascending rides
Audacious; but, that seat soon failing, meets
Flutters the vulturine plumes vainly, plumb down he drops
Ten thousand fathoms deep, and to this hour
Down had been falling, had not, I Ill chance,

Swelling, his tumult some of tumultuous cloud,
Instinct with fire and, fretting, hurried him
As many miles aloft.
"

In Milton's case, however, the truth is that he made the mistake
of trying to disturb the motive of the artistic purposes—
a fatal mistake, as we shall see when we come to speak of the
Nibelung story, to the last. And that mistake has

Though Vondel's mystery play of Lucifer is, in its execution
rhetorical more than poetical, it did, beyond all question, influence Milton's
"Paradise Lost." The former is the

"Better to reign in hell than serve in heaven"—

seems to have been taken bodily from Vondel's play, and Milton's
entire epic shows a study of it. While Marlowe's majestic move-

ments alone are traceable in Satan's speech (written some years before the rest of Paradise Lost, when the dramatic and not the poetic, the rhetorical and not the poetical, is uppermost). A
splendid amalgam not of the Mephistophiles but of the Faustus
of Marlowe and the Lucifer of Vondel. Vondel's play must have

influenced Milton's, peculiarity of his conception of human progress. Defective as the play is in execution, it is far
otherwise in motive. This motive, if we consider it aright, is
nothing less than an explanation of man's anomalous condition
in the grave of spirit, of his impotence, his lowly station, in fact,

that than the angels—in order that he may advance by means
of these very manacles which imprison him, in order that he
may ascend by the stair-case of the world, the ladder of fleshly conditions,
above those whom he once, perhaps, held as his gods. As regards the Odyssey, however, we need scarcely say that its motive
is merely artistic, not philosophic. And now we come to philosophic
motive.

Aristotle's power of thought is properly shown not in the
direct enunciation of ideas but in mastery over motive. Here
Aeschylus is by far the greatest figure in Western poetry—a proof
perhaps among many proofs of the Oriental strain of his genius.
Here, in the Agamemnon, in the Libation Bearers, in the Chorus
of the Lusiads, the conflict of thought with heart-thought is
occasionally shown. In his to the Orestes, it is as compared with such a play as

Othello or Lear. Notwithstanding the superficial exception
of Aeschylus, the truth seems to be that the faculty of developing a poetical
narrative from a philosophic thought is Oriental, and on
Milton's part, a great deal of the Galatea is the product of a
mind. Neither in Western drama nor in Eastern epic do we find, save in those rare cases as that of Vondel, anything like that power of developing a story from an idea which not only Jami but all the parable poets
of the Orient have exhibited.

In modern English poetry the motive of Shelley's dramatic
poem Prometheus Unbound is a notable illustration of what is here
contended. Starting with the full intent of developing a drama
on the lines of the Iliad and the Odyssey, he has worked out the
idea, which he says will be the "final goal of ill"—Shelley cannot finish his first three
hundred lines without shifting (in the curse of Prometheus) into
a Manicheanism as pure as that of Mames himself:—

"Heap on thy soul, by virtue of this curse,
Ill deeds, the Doing, beholding good;
Both infinite as is the universe."

According to the central thought of the poem human nature,
through the heroic protest and struggle of the human mind typified
by Prometheus, can at last dethrone that supernatural terror and
tyranny (Jupiter) which the human mind had itself invested. But,
after its dethronement (when human nature becomes infinitely
perfectible), how can the supernatural tyranny exist apart from
the human mind that imagined it? How can it be as "infinite as
the universe"?

The motive of Paradise Lost is assailed with much vigour by
Victor Hugo in his poem Religions et Religion. But when Hugo,
in the "castle of the hearts of all the faithful" of Milton's God, "sets
up an entirely French "Dieu" of his own and one just in the

him, we perceive how pardonable was Milton's failure after all. Compare such
difference of mental grip and such nebulosity of thought as of the Orestes, is as compared with such a play as

the strength of hand shown in the "Stillmammil" and "Aasel" of Jami, and

refused by the Sufi poets generally.

There is, however, one exception to this rule that Western poetry
is not only incapable of producing as to poetic motive

that refuses to be classified, though for entirely different reasons.
This is the Nibelung story, where we find unity of purpose and
also entire freedom of movement. We find combined here beauties
of the dramatic and of the epic, where a dramatic unity is also

the treatment of every other character. Each character is

the way by which the Kauravas defeated their relatives at dice and
refused to disgorge their winnings.

This Northern epic-tree, as we find it in the Icelandic sagas, the
remains themselves have watered; for it combines the virtues
of the epic of growth with those of the epic of art. Though not written in metre, it may usefully be compared with the epics of Orpheus and of the Homeric period. There are, however, differences from that world it is enlaid by a cordon of curses—by a zone of defant Flames more impregnable than that which girdled the land of the Theban. Norwegian, Swedish, and Icelandic folk-tale, are at work everywhere. In Scandinavia comes the old epic, whose circumference is but that of a woman's finger, encircles the whole mimic world of the sagaman as the Midget snake encircles the world of the earthworm. There is a strange grief in the people, and many causes, some of them traceable and some of them beyond all discovery—causes no doubt akin to those which gave birth to many of the beauties of other epics of growth. Originally Sigurd and Sigurd were the enemines of the hero, but now has vast been the artistic effect of the separation of the two! Again, there were several different versions of the story of Brynhild. The sagaman, finding all these versions too interesting and too much beloved to be discarded, adopted them all—worked them up into one legend, so that, in the Völsunga Saga we have a heroine possessing all the charms of goddess, demi-godness, earthy princess and amazon—a heroine surpassing perhaps in fascination all other heroines that have ever figured in poetry.

It is when we come to consider such imaginative work as this as a representation of the Teutonic mind, and what it may seem to us, that it becomes of the greatest interest. In speaking of the Nibelung story we do not, of course, speak of the German version, the Nibelungenlied, a fine epic still, though a degradation of the elder form. Between the two the differences are considerable, and the composition an excellent illustration of what has been just said upon the disturbance of motive in epic, and indeed in all poetic art. It is not merely that the end of the three principal characters, Sigurd (Siegfried), Gudrun (Karin), and Attila (Wotan) are entirely new; it is that the Icelandic version, by missing the blood-bath at Faar's hair, loses the pathetic situation of Gudrun's becoming afterwards an unwilling instrument of her husband's death; it is not merely that, on the other hand, the German version, by omitting the early love passages by Brynhild and Sigurd at Helles, misses entirely the tragic meaning of her story and the terrible hate that is binding them together; but that, as in each version the story is so exactly the opposite of the other that, while the German story is called (and very properly) "Kriemhilt's Revenge," the story of the Völsunga Saga might, with equal propriety, be called Forgiveness.

If it be said that, in both cases, the motive shows the same Titanic temper, that is because the Titanic temper is the special characteristic of the North-Western mind. The temper of the north, with its authority and its strength, is indebted to that energy which succeeds in the modern development of the great racial struggle for life. Although no epic, Eastern or Western, is without its gods and goddesses, and so a struggle upon apparently equal terms—it must not be supposed that the warring of conflicting forces which is the motive of Eastern epic has much real relation to the warring of gods and goddesses that rules in the modern Western epic. And, as regards the machinery of epic, there is, we suspect, a deeper significance than is commonly apprehended in the fact that the Satan or Shaitan of the Eastern world becomes in Vedell and Milton's sublime Titan who attracts to himself the admiration which in Eastern poetry belongs entirely to the authority of heaven. In Asia, save perhaps among the pure Arabs of the desert, underlying all religious forms, there is apparent a temper of resigning to the irresistible authority of heaven. And as regards the Aryans it is probable that the Titanic temper—the temper of revolt against authority—did not begin to show itself till they had moved across the Caucasus. But what comes of this question of fact is the more north-west the more vigorously this temper asserted itself, the more man grew in his attitude towards the gods, till at last in the Scandinavian cycle he became their equal and struggled against them, in the epic of heaven against the assaults of hell. Therefore, as we say, the student of epic poetry must not suppose that there is any real parallel between the attitude of Vishnu (as Rama) towards Ravana and Zeus towards Prometheus. From the very fact that the Caucaic race produced the heroes towards Odin in Scandinavian poetry. Had Ravana been clothed with a properly constituted authority, had he been a legitimate god instead of a demon, the Eastern demon was probably more estimable and less likely to come in and the world would have been spared one at least of its enormous epics. Indeed, the Ravana of the Ramâyana answers somewhat to the Faàr of the Völsunga Saga; and to plot against a demigod. But such a temper against an Eastern epic, however, is quite beyond us here.

Nor can we do more than glance at the Kalevala. From one point of view that group of ballads might be taken, no doubt, as a simple record of how the men of Kalevala were skilled in capturing the sisters of the Pojobila men. But from another point of view the struggle which is the female seems typified in this of the Rainbow" sitting upon her glowing arc and weaving her golden threads, while the hero is doing battle with the malevolent forces of nature.

But it is in the Nibelung story that the temper of Western epic is at its best—the temper of the simple fighter, whose business it is to fight. The ideal Western fighter was not known in Greece till ages after Homer, when in the pass of Thermopylae the com-

mands of Leonidas comprised their long hair in the sun. The business of the fighter in Scandinavian epic is to yield to no power whatsoever, whether of earth or heaven or hell—to take a buffet from the hand of the enemy and to return it; to look Destiny herself in the face, crying out for quarter neither to gods nor demons nor Norns. This is the true temper of pure "heroic poetry" as it has hitherto flourished on this side the Caucasus—the temper of the fighter who is invincible because he feels that Fate herself falters not. The hero of the true strain—defies the fighter who feels that the very Norns themselves must cringe at last before the simple courage of man standing naked and bare of hope against all armies, whether of heaven or hell or doom. The proud heroes of the Völsung Saga utter no moans and shed no Homeric tears, knowing as they know that the day prophesied is sure when, should to shoulder, gods and men shall stand up to fight the entire brood of night and evil, storming the very gates of Asgard.

That this temper is not the highest from the ethical point of view is no doubt true. Against the beautiful resignation of the German poems, the physical force of Western, and the passion of the Nordic, we may perhaps be allowed to call it the "Great Lyric." The Great Lyric must be religious—it would, it seem, be an outpouring of the soul, not towards man but towards God, like that of the God-intoxicated prophets and psalmists of Scripture. Even the lyric fire of Pindar owes much to the fact that he had a childlike belief in the myths to which so many of his contemporaries had begun to give a languid assent. But there is nothing in Pindar, or indeed somewhere in Greek poetry, like the rapturous song, combining unconscious power with unconscious grace, which we have called the Great Lyric. It might perhaps be said indeed that the Great Lyric is a Northern Hindu. But, although we could hardly expect to find it among those whose language, complex of syntax and alive with self-conscious inferences, bespeaks the scientific knowlingness of the Western mind, to call the temper of the Great Lyric broadly "Asistic" would be rash. It seems to belong as a birthright to those descendants of Sham who, yearning always to look straight into the face of God and live, could (when the Great Lyric was sung) see not much else.

Though two of the artistic elements of the Great Lyric, unconsciousness and power, are no doubt plentiful enough in India, the element of grace is lacking for the most part. The Hindu and the Persian are both deeply attached to the familiar and the traditional, and are opposed with Semitic hymns. And as to the Persians, they, it would seem, have the grace always, the power often, but the unconsciousness almost never. This is inevitable if we consider for a moment the chief characteristic of the Persian imagination—an imagination whose wings are not so much "bright with beauty" as heavy with it—heavy as the wings of a golden pheasant steeped in beauty like the "tiger-moth's deep damasked wings." Now beauty of this kind does not go to the making of the Great Lyric.

Then there comes that poetry which, being ethnologically Semitic, might be supposed to exhibit something of the least of the two qualities of the Arabic. But, whatever may be said of the oldest Arabic poetry, with its deep sense of fate and pain, it would seem that nothing can be more unlike the Hebrew temperament and the Arabian temper as seen in later poets. It is not with Hebrew but with Persian poetry that Arabian poetry can
be usefully compared. If the wings of the Persian imagination are heavy with beauty, those of the later Arabian imagination are bright with beauty—brilliant as an Eastern butterfly, quick and agile as a dragon-fly or a humming-bird. To the eye of the Persian poet the hues of earth are (as Firdausi says of the garden of Afrasiab) "like the tapestry of the kings of Ormuz, the clouds of Onomoki, and the lilies of the brooks are the essence of roses." And to the later Arabian no less than to the Persian is the earth beautiful; but it is the clear and sparkling beauty of the earth as she "wakes up to life, greeting the Sabæan morning"; we feel the light more than the colour. But it is neither the Persian's instinct for beauty nor the Arabian's quenchless wit and exhaustless animal spirits that go to the making of the Great Lyric; far from it. In a word, the Great Lyric, as we have said, cannot be assigned to the Asiatic temper generally any more than it can be assigned to the European.

In the poetry of Europe, if we cannot say of Pindar, devout as he is, that he produced the Great Lyric, what can we say of any other European poet? The truth is that, like The Great Drama, so straight and so warm does it seem to come from the heart of man in its highest moods that we scarcely feel it to be literature at all. Passing, however, from this supreme expression of lyrical imagination, we come to the artistic ode, upon which subject the present writer can only reiterate here what he has more fully said upon a former occasion. Whatever may have been said to the contrary, enthusiasm is, in the nature of things, the very basis of the ode; for the ode is a mono-drama, the actor in which is the poet himself; and, as Marmontel has well pointed out, if the actor in the monodrama is not affected by the sentiments he expresses, the ode must be cold and lifeless. But, although the ode is a natural poetic method of the poet considered as prophet—although it is the voice of poetry as a fine frenzy—it must not be supposed that there is anything lawless in its structure. "Pindar," says the Italian critic Gravina, "launches his verses upon the bosom of the sea; he spreads out all his sails; he confronts the tempest and the rocks; the waves arise and are ready to engulf him; already he has disappeared from the spectator's view; when suddenly he springs up in the midst of the waters, and reaches happily the shore." Now it is this Pindaric disconnection, this Pindaric unrestrainedness, that is the matter, which has led poets to attempt to imitate him by adopting an unrestrained as to form. Although no two odes of Pindar exhibit the same metrical structure (the Aeolian and Lydian rhythms being mingled with the Doric in different proportions), yet each ode is in itself obedient, severely obedient, to structural law. This we feel; but what the law is no metricist has perhaps ever yet been able to explain.

It was a strange misconception that led people for centuries to use the word "Pindaric" and irregular as synonymous terms; whereas the very essence of the odes of Pindar (of the few, alas! which survive to us) is their regularity. There is no more difficult form of poetry than this, and for this reason: when in any poetical composition the metres are varied, there must, as the present writer has before pointed out, be a reason for such freedom, and that reason is properly subjective—the varying form must embody and express the varying emotions of the singer. But when these metrical variations are governed by no subjective law at all, but by arbitrary rules supposed to be evolved from the practice of Pindar, then that very variety which should aid the poet in expressing his emotion crystallizes it and makes the ode the most rigid of all compositions. Great as Pindar undoubtedly is, it is deeply to be regretted that no other poet survives to represent the triumphal ode of Greece—the degenerations of his subject matter are so wide, and his volatility is so great.

In modern literature the ode has been ruined by theories and experiments. A poet like La Mothe, for instance, writes execrable odes, and then writes a treatise to prove that all odes should be written on the same model. There is much confusion of mind prevalent among poets as to what is and what is not an ode. All odes are, no doubt, divisible into two great classes: those which, following an arrangement in stanzas, are commonly called regular, and those which, following no such arrangement, are commonly called irregular.

We do not agree with those who assert that irregular metres are of the nature of "innovation." Contrariwise, we believe that in modern prosody the arrangement of the rhymes and the length of the lines in any rhymed metrical passage may be determined either by a fixed stanzaic law or by a law infinitely deeper—by a law which impels the soul, in a state of perfect, even if it be impossible, to seize hold of every kind of metrical aid, such as rhyme, caesura, &c., for the purpose of accentuating and marking off each shade of emotion as it arises to the demands of stanza. But between the irregularity of makeshift, some of which we find it in Cowley and his imitators, and the irregularity of the "fine frenzy" of such a poem, for instance, as Coleridge's "Khub Khan," there is a difference in kind. Strange as it may seem, but that in this unique lyric Khub Khan, descriptive of imaginative landscape, that an English poet has at last conquered the crowning difficulty of writing in irregular metres. Having broken away from all restraints of couplet and stanza—having caused his rhymes and pauses to fall just where and just when the emotion demands that they should fall, scorning the exigenes of makeshift no less than the exigencies of stanza—he has found what every writer of irregular English odes longs for, a mode as entrancing in vain, and in the same time as inscrutable, as the music of the winds or of the sea.

The prearranged effects of sharp contrasts and antithetical movement, which as something has previously been able to compass, do not of course come under the present definition of irregular metre at all. If a metrical passage does not gain its effect immemorially by being written independently of stanza, but by a certain rhythm, there is then the great charm of the music of all verse, as distinguished from the music of prose, is ineluctableness of cadence. In regular metres we enjoy the pleasure of feeling that the rhymes will inevitably fall under the couplet or stanza. But if the passage flows independently of these, it must still flow inevitably—it must, in short, show that it is governed by another and a yet deeper force, the inevitableness of emotional expression. The lines must be kept together, but are not necessarily to be fixed by the metre. Of course, such an emotional necessity was there for the following rhyme-arrangement?

"Me heart is at your disposal, my head hath its coronal. The fulness of your bliss I feel—I feel it all. Oh, evil day! if I were waked, while earth herself is adorning, this morning more And the children are culling, on every side, in a thousand valleys far and wide, fresh flowers, Beautiful as is the substance of this entire passage, so far from gaining, it loses by rhyme—loses, not in perspicuity, for Wordsworth like all his contemporaries (except Shelley) is mostly perspicuous, but that in metrical emphasis the quest of which is one of the impulses of the ode, the poet to express himself with the least number of defects, this famous ode of Wordsworth's is the finest irregular ode in the language; for, although Coleridge's "Ode to the Departing Year" excels it Pindaric fire, it is below Wordsworth's for two reasons. First, it is almost very modern. Among the writers of English irregular odes, next to Wordsworth, stands Dryden. The second stanza of the Ode for St Cecilia's Day is a grand triumph.

Leaving the irregular and turning to the regular ode, it is natural to divide these into two classes: (i) those which are really Pindaric in so far as they consist of strophes, antistrophes and epiodes, variously arranged, according to those which consist of a regular succession of regular stanzas. Perhaps all Pindaric odes tend to show that this form of art is in English a mistake. It is easy enough to write one stanza and call it a strophe, another in a different movement and call it a couplet, a third in a different movement still and call it an epode. But in modern prosody, disconnected as it is from musical and from terpsichorean science, what are these? No poet and no critic can say. What is requisite is that the ear of the reader should catch a great metrical scheme, of which these three varieties of movement
are necessary parts—should catch, in short, that inevitableness of structure upon which we have already touched. In order to justify a poet in writing a poem in three different kinds of movement, governed by no musical and no tercetschorus necessity, a new study of another kind should make itself evident; that is, the metrical wave moving in the strophe should be metrically answered by the counter-wave moving in the antistrophe, while the epode—which, as originally conceived by Sannazarus, was a mere assemblage of short unrhymed lines (the place of the antistrophic musical phrase had been taken by the antistrophe)—should clearly, in a language like ours, be a blended echo of these two. A mere metrical contrast such as some poets laboriously attempt to create will not do. And if the reply to this criticism be that in Pindar himself and many of the other Greek verses, this place and time where the strophic musical phrase had been taken by the antistrophe—should be apparent, that is the strongest possible argument in support of our position. If indeed the metrical scheme of Pindar is not apparent, then it is only because we are not looking for chaos or subordination to the lost musical scheme of the musician. It has been contended, and is likely enough, that this musical scheme was simple—as simple, perhaps, as the scheme of a cathedral chime; but it is not apparent that this is something which is not clear in what the moment ceased to be chanted, the words strophe, antistrophe, and epode lost the musical value they had among the Greeks, and pretended to a complex metrical value which their actors did not possess, and which, obviously, would have to justify the new and not the old. It is not even possible to say that the poet's arrangement should justify itself by disclosing an entire metrical scheme in place of the musical scheme to which the musical elements are subordinated. Even if the poet were a sufficiently skilled metrist to compass a scheme embracing a wave, an answering wave, and an echo gathering up the tones of each, i.e., the strophe, the antistrophe and the epode, the ear of the reader, unaided by the musical emphasis which supported the rhythms of the old choral lyric, is, it should seem, incapable of gathering up and remembering the sounds further than the position of each wave which is in each of the three strophes but a return to the strophe. That is to say, an epode, as alternating in the body of the modern ode, is a mistake; a single epode at the end of a group of strophes and antistrophes (as in some of the ode of Hesiod) is a mistake. The great difficulty of the English ode is that of preventing the apparent spontaneity of the impulse from being marred by the apparent artifice of the form; for, assuredly, no writer subsequent to Coleridge to Keats would dream of writing an ode on the Horatian principles adopted by Warton, and even by Collins, in his beautiful "Ode to Evening."

Of the second kind of regular odes, those consisting of a regular succession of stanza, the so-called odes of Sappho are, of course, so transcendent that no other amatory lyrics can be compared with them. Never before these songs were sung and never since did the human soul, in the grip of passion, utter the sentiments which here are laid bare; the only point of view, in directness, in lucidity, in that high imperious verbal economy which only nature herself can teach the artist, she has no equal, and none worthy to take the place of it, in the literature of England. But, in modern poetry, there are some magnificent examples of this simple form of ode in English poetry—Spenser's immortal "Epithalamion" leading the way in point of time, and probably also in point of excellence.

Fervor being absolutely essential, we think, to a great English ode, fluidity of metrical movement can never be dispensed with. The more bilowry the metrical waves the better suited are they to an ode, and the reader is led by referring to Coleridge's "Ode to France" (the finest ode in the English language, according to Shelley), and giving special attention to the first stanza—to the way in which the first and second wave are taken by the reader, and the first quatrains leap up again on the double rhymes (which are expressly introduced for this effect), and goes bounding on, billow after billow, to the end of the stanza. Not that this fine art is quite free from fault. If we except Spenser and, in one instance, Collins, it can hardly be said that any English writer before Shelley and Keats produced odes independent of rhetoric such as is supposed to accompany poetry. But from Coleridge's "Ode to the West Wind" and Keats's odes "To a Nightingale," and "On a Grecian Urn," they are entirely free from rhetorical flavour. Notwithstanding that in the "Ode on a Grecian Urn," Keats has not made the arrangement peculiar to the others, while the second stanza of the "Ode to a Nightingale" varies from the rest by running on four rhyme-sounds instead of five, vexing the ear at first by disappointed expectation, the two odes are, after Coleridge's "Franco," the finest regular odes perhaps in the English language.

With regard to the French ode, Malherbe was the first writer who brought it to perfection. Malherbe showed also more variety of mood than it is the fashion just now to credit him with. This may be especially noted in his "Ode to Louis XIII." His disciple Racan is not of much account. There is certainly much vigour in the odes of Rousset. But it is not till we reach Victor Hugo that we realize what French poetry can achieve in this line; and contemporary poetry can hardly be examined here. We may say, however, that some of Hugo's odes are truly magnificent. As a general rule, odes are short drinking songs of which the French make the most. The Song.

The Song. The simplicity of grammatical structure which is foreign to many natures—that mastery over direct and simple speech which only true passion and feeling can give, and which "coming from the heart goes to the heart." Without going so far as to say that no man is a poet who cannot write a good song, it may certainly be said that no man can write a good song who is not a good poet. In modern times we have, of course, nothing in any way representing those choral dance-songs of the Greeks, which, originating in the primitive Cretan war-dances, became, in Pindar's time, a splendid form of song and dance. Nor have we anything exactly representing the "canto fermo" which goes to make up the passages of song between the short drinking songs of which Terpander is said to have been the inventor. That these stanzas were written, not only by poets like Alcaeus, Anacreon, Praxilla, Simonides, but also by Sappho and by Pindar, shows in what high esteem they were held by the Greeks. These songs seem to have been as brief as the stornelli of the Italian peasant. They were accompanied by the lyre, which was handed from singer to singer as the time for each cecolin came round.

With regard to the stornello, many critics seem to confound it with the rispetto, a very different kind of metricality. The Italian stornello consists of a stanza of inter-rhyming lines ranging from six to ten in number, but often not exceeding eight. The Tuscan and Umbrian stornello is much shorter, consisting, indeed, of a hemistich naming some natural object which suggests the motive of the little poem. The nearest approach to the Italian stornello appears to be, not the rispetto, but the Welsh triban.

Perhaps the mere difficulty of rhyming in English and the facility of rhyming in Italian must be taken into account when we inquire why there is nothing in Scotland—of course there could be nothing in England—answering to the nature-poetry of the Italian peasant. Most of the Italian rispetti and stornelli seem to be meant to improve in animated life, and not to be difficult as to improvise is easy in Italian. Nothing indeed is more interesting than the improvisatorial poetry of the Italian peasants, such as the canzone. If the peasyant discover who is the composer of a canzone, they will not sing it. The speciality of Italian peasant poetry is that the symbol which is mostly erotic is of the purest and most tender kind. A peasant girl will improvise a song as impassioned as "Come into the Garden, Maid," and as free from unwieldy tone.

With regard to English songs, the critic cannot but ask—Wherein lies the lost ring and charm of the Elizabethan song-writers? Since the Jacobean period we have, at least, not many arrangements of the kind. In the art of writing real songs as distinguished from mere book songs between songs to be sung and songs to be read there is in our time a difference as wide as that which exists between plays for the closet and plays for the boards. Heartiness and melody—the two requisites of a song which can never be dispensed with—can rarely be compassed, it seems, by one and the same individual. In both these qualities the Elizabethan poets stand pre-eminent, though even with them the melody is not so singable as it might be made. Since their time heartiness has, perhaps, been a Scottish rather than an English endowment of the song-writer. It is difficult to imagine an Englishman writing a song like "Tullechugorun" or a song
like "Maggie Lauder," where the heartiness and impulse of the poet's mood conquer all impediments of close vowels and rugged consonantal combinations. Of Scottish song-writers Burns is, of course, the head; for the songs of John Skinner, the heartiest song-writer that has appeared in Great Britain (not excluding Herrick), are too few in number to entitle him to be placed beside a poet so prolific in heartiness and melody as Burns. With regard to Campbell's heartiness, this is quite a different quality from the heartiness of Burns and Skinner, and is in quality English rather than Scottish, though, no doubt, it is of a fine and rare strain, especially in "The Battle of the Baltic." His songs illustrate an infirmity which even the Scottish song-writers share with the English—a defective sense of that true song-warble which we get in the stornell and rispetto of the Italian peasants. A poet may have heartiness in plenty, but if he has that love of consonantal effects which Donnæ displays he will never write a first-rate song. Here, indeed, is the crowning difficulty of song-writing. An extreme simplicity of structure and of diction must be accompanied by an instinctive apprehension of the melodic capabilities of verbal sounds, and of what Samuel Lover, the Irish song-writer, called "singing" words, which is rare in this country, and seems to belong to the Celtic rather than to the Saxon ear. "The song-writer," says Lover, "must frame his song of open vowels with as few guttural or hissing sounds as possible, and he must be content sometimes to sacrifice grandeur and vigour to the necessity of selecting singing words and not reading words." And he exemplifies the distinction between singing words and reading words by a line from one of Shelley's songs—

"The fresh earth in new leaves drest,

where nearly every word shuts up the mouth instead of opening it." But closeness of vowel sounds is by no means the only thing to be avoided in song-writing. A phrase may be absolutely unsingable, though the vowels be open enough, if it is loaded with consonants. The truth is that in song-writing it is quite as necessary to avoid a consonantal "Spanish" or an English "French" like ours, to attend to the consonants as to the vowels; and perhaps the first thing to avoid in writing English songs is the frequent recurrence of the sibilant. But this applies to all the brief and quintessential forms of poetry, such as the sonnet, the elegy, &c.

As to the elegy—a form of poetic art which has more relation to the objects of the external world than the song, but less relation to these than the stornello—its scope seems to be wide indeed, as practised by such various writers as Tyrtaeus, Theognis, Catullus, Tibullus, and our own Gray. It may almost be said that perfection of form is more necessary here and in the sonnet than in the song, inasmuch as the
distinctive sensations are more pronounced. Hence even such apparent miniatiae as those we have hinted at above must not be neglected here.

We have quoted Dionsius of Halicarnassus in relation to the arrangement of words in poetry. His remarks on sibilants are

Phonetic.

"are equally deserving of attention. He goes so far as to say that he is entirely disagreeable, and, when it often recurs, insupportable. His sound seems to him to be more appropriate to the beast than to man. Hence certain writers, he says, often avoid it, and employ it with regret. Some, he tells us, have composed entire odes without it. But if sibilation is a defect in Greek, it is much more so in English poetry, where the consonants dominate, though it will be only specially noticeable in the brief and quintessential forms such as the song, the sonnet, the elegy. Many poets only attend to their sibilants when these echo the rhythm. To write even the briefest song without a sibilant would be a tour de force; to write a good one would no doubt be next to impossible. It is singular that the only metricist who ever attempted it was "Thelwall," the friend of Lamb and Coleridge, and editor of the famous "Champion" newspaper, where many of Lamb's epigrams appeared. Thelwall gave much attention to metrical questions, and tried his hand at various metres though "Cire" is a subject often discussed. It is certain that he had a very remarkable critical insight into the rationale of metrical effects, and his "Song without a Sibilant" is extremely neat and ingenious. Of course, however, it would be mere pedantry to exaggerate this objection to sibilants even in these brief forms of poetry.

Poggendorff—Poggio

POGGENDORFF, J ohn Christian (1796-1877), German physicist, was born in Hamburg on the 20th of December 1796. His father, a wealthy manufacturer, having been all but ruined by the French siege, he had, when only sixteen, to apprentice himself to an apothecary in Hamburg, and when twenty-two began to earn his living as an apothecary's assistant in Itzehoe. Ambition and a strong inclination towards a scientific career led him to throw up his business and remove to Berlin, where he entered the university in 1820. Here his abilities were speedily recognized, and in 1823 he was appointed meteorological observer to the Academy of Sciences. Even at this early period he had conceived the idea of founding a physical and chemical scientific journal, and the realization of this plan was hastened by the sudden death of L. W. Gilbert, the editor of "Gilbert's Annalen der Physik, in 1824. Poggendorff immediately put himself in communication with the publisher, Barth of Leipzïg, with the result that he was installed as editor of a scientific journal, "Annalen der Physik and Chemie," which was to be a continuation of Gilbert's "Annalen on a somewhat extended plan. Poggendorff was admirably qualified for the post. He had an extraordinary memory, well stored with scientific knowledge, both modern and historical, a cool and impartial judgment, and a strong preference for facts as against theory of the speculative kind. He was thus able to throw himself into the spirit of modern experimental science. He possessed in abundant measure the German virtue of orderliness in the arrangement of knowledge and in the conduct of business. Further he had an engaging geniality of manner and much tact in dealing with men. These qualities soon made Poggendorff's "Annalen" the foremost scientific journal in Europe.

In the course of his fifty-two years' editorship of the "Annalen" Poggendorff could not fail to acquire an unusual acquaintance with the labours of modern men of science. This knowledge, joined to what he had gathered by historical reading of equally unusual extent, he carefully digested and gave to the world in his "Biographisch-literarischer Handwörterbuch zur Geschichte der exacten Wissenschaften, containing notices of the lives and labours of mathematicians, astronomers, physicists, and chemists, of all peoples and all ages. This work contains an astounding collection of facts invaluable to the scientific biographer and historian. The first two volumes were published in 1863; after his death a third volume appeared in 1899, covering the period 1858-1883, and a fourth in 1904, coming down to the beginning of the 20th century.

Poggendorff was a physicist of high although not of the very highest rank. He was wanting in mathematical ability, and never displayed in any remarkable degree the still more important power of scientific generalization, which, whether accompanied by mathematical skill or not, never fails to mark the highest genius in physical science. He was, however, an able and conscientious experimenter, and was very fertile and ingenious in devising physical apparatus. By far the greater and more important part of his work related to electricity and magnetism. His literary and scientific reputation speedily brought him honourable recognition. In 1833 he was made royal professor, in 1834 Hon. Ph.D. and extraordinary professor in the university of Berlin, and in 1839 member of the Berlin Academy of Sciences. Many offers of ordinary professorships were made to him, but he declined them all, devoting himself to his duties as editor of the "Annalen," and to the pursuit of his scientific researches. He died at Berlin on the 24th of January 1877.

Poggio (1380-1459). Gian Francesco Poggio Bracciolini, Italian scholar of the Renaissance, was born in 1380 at Ternano, a village in the territory of Florence. He studied Latin under John of Ravnella, and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of MSS. brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolo de' Niccolì befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefits conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable.
that, while he held his office in the curia through that momentous period of fifty years which witnessed the Councils of Constance and of Basel, and the final restoration of the papacy under Nicholas V., his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Weingarten, and above all St Gall, restored many lost masterpieces of Latin literature, and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus, and the commentaries of Asconius Pedianus at St Gall. MSS. of Lucretius, Columella, Silius Italicus, Manilius and Vitruvius were unearthed, copied by his hand, and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's Oration for Caecina, at Monte Cassino a MS. of Frontinus. He also could boast of having recovered Annius Marcubulus, Nonius Marcellus, Probus, Flavius Caper and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud, as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfield. Resolute in recognizing erudition as the chief concern of man, he sighed over the folly of popes and princes, who spent their time in wars and ecclesiastical disputes when they might have been more profitably employed in reviving the lost learning of antiquity. This point of view is eminently characteristic of the earlier Italian Renaissance. The men of that nation and of that epoch were bent on creating a new intellectual atmosphere for Europe by means of vital contact with antiquity. Poggio, like Aeneas Sylvius Piccolomini (Pius II.), was a great traveller, and wherever he went he brought enlightened powers of observation trained in liberal studies to bear upon the manners of the countries he visited. We owe to his pen curious remarks on English and Swiss customs, valuable notes on the remains of antique art in Rome, and a singularly striking portrait of Jerome of Prague as he appeared before the judges who condemned him to the stake. It is necessary to dwell at length upon Poggio's devotion to the task of recovering the classics, and upon his disengagement from all but humanistic interests, because these were the most marked features of his character. In order to effectively embrace the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises, a panegyrist of the dead, a violent impugner of the living, a translator from the Greek, an epistolographer and grave historian and a facetious compiler of fabliaux in Latin. On his moral essays it may suffice to notice the dissertations On Nobility, On Vicissitudes of Fortune, On the Misery of Human Life, On the Infidelity of Princes and On Marriage in Old Age. These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact embedded in a mass of commonplace meditation, and for some occasionally brilliant illustrations. Poggio's History of Florence, written in avowed imitation of Livy's manner, requires separate mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which derived so much of Bruni's, Carlo Aretino's and Bembo's work of historical weight. A somewhat different criticism must be passed on the Facetiae, a collection of humorous and indecent tales expressed in such Latinity as Poggio could command. This book is chiefly remarkable for its unsparring satires on the monastic orders and the ecclesiastic clergy. It is also noticeable as illustrating the latinating tendency of an age which gave classic form to the lightest essays of the fancy. Poggio, it may be observed, was a fluent and copious writer in the Latin tongue, but not an elegant scholar. His knowledge of the ancient authors was wide, but his taste was not select, and his erudition was superficial. His translation of Xenophon's Cyropaedia into Latin cannot be praised for accuracy. Among contemporaries he passed for one of the most formidable polemical or gladiatorial rhetoricians; and a considerable section of his extant works are invectives. One of these, the Dialogue against Hypocrates, was aimed in a spirit of vindictive hatred at the vices of ecclesiastics; another, written at the request of Nicholas V., covered the anti-pope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invective which he discharged against the Wilful Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire; and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla Poggio found his match; and Italy was amused for years with the spectacle of their indecent combats. To dwell upon such literary infamies would be below the dignity of the historian, were it not that these habits of the early Italian humanists imposed a fashion upon Europe which extended to the later age of Scaliger's confections with Scippius and Milton's with Salmusius. The greater part of Poggio's long life was spent in attendance to his duties in the papal curia at Rome and elsewhere. But about the year 1452 he finally retired to Florence, where he was admitted to the burghership, and on the death of Carlo Arethino in 1453 was appointed chancellor and historiographer to the republic. He had already built himself a villa in Valdarno, which he adorned with a collection of antique sculpture, coins and inscriptions. In 1435 he had married a girl of eighteen named Vagia, of the famous Buondelmonte blood. His declining days were spent in the discharge of his honourable Florentine office and in the composition of his history. He died in 1439, and was buried in the church of Santa Croce. A statue by Donatelto and a picture by Antonio del Pollajoluelo remained to commemorate a citizen who chiefly for his services to humanistic literature deserved the notice of posterity.

Poggio's works were printed at Basel in 1538, "ex aedibus Henrici Petri. Dr Shepherd's Life of Poggio Bracciolini (1802) is a good authority on his biography. For his position in the history of the revival, see Voigt's Wiederbelebung des classischen Alterthums, and Symonds' Renaissance in Italy. (J. A. S.)

POGLIZZA (Serbo-Croatian, Poljica), a tract of mountainous land in Dalmatia, Austria; formerly the seat of an independent republic. The territories of Poglizza lay chiefly within the south-easterly curve made by the river Cetina before it enters the Adriatic at Allerthums. The chief, however, aimed at the fastnesses of the Mosser range (500 ft.) and the fertile strip of coast from Almissa to Stobrez, 10 m. W.N.W. The inhabitants lived in scattered villages, each ruled by its count, and all together ruled by the supreme count. These officers, with the three judges, were always of noble birth, though elected by the whole body of citizens. There were two orders of nobles; the higher, including about 20 families, claimed Hungarian descent; the lower, claiming kinship with the Bosnian aristocracy. Below these ranked the commoners and the serfs. At a very early date the warlike highlanders of Poglizza became the friends and allies of the Almisan corsairs, who were thus enabled to harass the seaborne trade of their neighbours without fear of a sudden attack by land. Almissa received a charter from Andrew II. of Hungary in 1207, and remained under the nominal protection of Hungary until 1444, when both Almissa and Poglizza accepted the suzerainty of Venice, while retaining their internal freedom. The population of Poglizza numbered 6566 in 1806. In the following year, however, the republic incurred the enmity of Napoleon by rendering aid to the Russians and Montenegrins in Dalmatia; and it was invaded by French troops, who plundered its villages, massacred its inhabitants, and finally deprived it of independence.

See the Annuario Dalmatico for 1885 (published at Zara); and A. Fortis, Travels into Dalmatia (London, 1778).
POINCARÉ, RAYMOND (1854-), French statesman, was born at Bar-le-Duc on the 20th of August 1854, the son of Nicolas Antoine Hérouard Poincaré, a distinguished civil servant and member of the Cabinet of the Republic. The Paris was called to the Paris bar, and was for some time law editor of the Valois. He had served for over a year in the department of agriculture when in 1859 he was elected deputy for the Meuse. He made a great reputation in the Chamber as an economist, and sat on the budget commissions of 1867-1870 and 1892. He was minister of education, fine arts and religion in the first cabinet (April-Nov. 1863) of Charles Dupuy, and minister of finance in the second and third (May 1864-Jan. 1865). In the succeeding Ribot cabinet Poincaré became minister of public instruction. Although he was excluded from the Radical cabinet which followed, the proposed scheme of duties he had been prepared to cooperate, but the new ministry was based upon his proposals of the previous year. He became vice-president of the cabinet in the autumn of 1865, and in spite of the bitter hostility of the Radicals retained his position in 1866 and 1867. In 1866 he returned to the ministry of finance in the short-lived Sarrien ministry. Poincaré had retained his practice at the bar during his political career, and he published several volumes of essays on literary and political subjects.

His brother, Lucien Poincaré (b. 1862), famous as a physicist, became inspector-general of public instruction in 1902. He is the author of La Physique moderne (1906) and L'Electricité (1907). Julien Henri Poincaré (b. 1854), a distinguished physician, belongs to another branch of the same family.

POINSETTIA. The Poinsettia pulcherrima of gardens (Euphorbia pulcherrima) of botanists, a native of Mexico and Central America, with its brilliant scarlet bracts, stands unrivalled amongst decorative plants. The white-bracted sort, var. alba, is not so effective, but the double-flowered, var. plenissima, in which the brilliant inflorescence is branched, is as brilliant as the type, and keeps long in flower. They are increased by cuttings in spring, which when taken off with a heel strike freely in brisk heat. They require good turfy loam, with an addition of one-sixth of leaf-mould and a little sand, and should be kept in a heat of from 65° to 70° at night, with a rise of 10° by day. To prevent their growing lanky, they should be kept with their heads almost touching the glass; and as the pots get filled with roots they must be shifted into others, 7 or 8 in. in diameter. About August they may be inured to a heat of 50° at night, and should be brought to bear air night and day whilst the weather is warm, or they may be placed out of doors for a month under a south wall in the full sun. This treatment matures and prepares them for flowering. In autumn they must be removed to a house where the temperature is 50° at night, and by the end of September some of them may be put in the stove, where they will come into flower, the remainder being placed under heat later for succession. When in bloom they may be kept at about 55° by night, and so placed will last longer than if kept in a higher temperature.

POINSET, LOUIS (1777-1859), French mathematician, was born at Paris on the 3rd of January 1777. In 1794 he became a scholar at the École Polytechnique, which he left in 1796 to act as a civil engineer. In 1804 he was appointed professor of mathematics at the Lycée, in 1809 professor of analysis and mechanics, and in 1816 examiner at the École Polytechnique. On the death of J. L. Lagrange, in 1813, Poinset was elected to his place in the Académie des Sciences; and in 1840 he became a member of the superior council of public instruction. In 1846 he was made an officer of the Legion of Honour; and on the formation of the senate in 1852 he was chosen a member of that body. He died at Paris on the 4th of December 1859.

Poinset's earliest work was his Éléments de statique (1803; 9th edition, 1848), in which he introduces the idea of statical couples and investigates their properties. In the Théorie nouvelle de la rotation des corps (1834) he treats the motion of a rigid body geometrically, and shows that the most general motion of such a body can be represented at any instant by a rotation about an axis combined with a translation parallel to this axis, and that any motion of a body of which one point is fixed may be produced by the rolling of a cone fixed in the body on a cone or cylinder. The theory of the motion of a rigid body had in every case been purely analytical, and so gave no aid to the formation of a mental picture of the body's motion; and the great value of this work lies in the fact that, as Poinset himself says in the introduction, it enables us to represent to ourselves the motion of a rigid body as clearly as that of a moving point. In addition to publishing a number of works on geometrical and mechanical subjects, Poinset also contributed a number of papers on pure and applied mathematics to L'Année Éclectique and other scientific periodicals.

POINT PLEASANT, a town and the county-seat of Mason county, West Virginia, U.S.A., on the Ohio river, at the mouth of the Kanawha river, and about midway between Pittsburgh and Cincinnati. Pop. (1900) 1359; (1910) 2054. It is served directly by the Baltimore & Ohio and the Kanawha & Michigan (controlled by the Hocking Valley railways), and by the Hocking Valley railway on the opposite side of the Ohio river. The Kanawha river is navigable (by the use of locks and dams) for 90 m. above the town, and Point Pleasant is a re-shipping point for Kanawha coal. Coal and salt are mined in the vicinity, but the surrounding country is principally agricultural.

Point Pleasant was the site of the battle of Point Pleasant in "Lord Dunmore's War," was fought here on the 10th of October 1774 between about 1100 Virginia militiamen, under General Lewis (c. 1720-1781), and about 1000 Shawnees and their allies, under their chief, Cornstalk (c. 1720-1777). Lewis had been ordered to meet Lord Dunmore here with a body of militiamen (recruited from Botetourt, West Augusta and Fincastle counties), but when he reached the mouth of the Kanawha, after marching 160 m. from Fort Union (now Lewisburg, W. Va.), Dunmore's force, which was to have gone over the Braddock trail to Fort Pitt, and thence down the Ohio river, had not arrived. Early on the morning of the 10th the Indians suddenly attacked, and the battle continued fiercely throughout the day. At night the Indians crossed the Ohio river, leaving behind many of their dead. The whites lost about 144 in killed and wounded, Colonel Charles Lewis (1733-1774), a brother of the commanding officer, being among the former. In December Lord Dunmore concluded a treaty with the Indians, by which they surrendered their claim to lands south of the Ohio and agreed not to molest whites travelling to the western country. The battle, which overawed the Indians, and the treaty, which was not seriously broken for three years, made possible the rapid settlement of the western country, especially of Kentucky, during the early years of the War of Independence. Four years before the battle the Virginia House of Burgesses had awarded to General Lewis, for his earlier services in the French and Indian War, 6876 acres of land, including the

1 General Lewis was born in Donegal, Ireland, served with Washington at Fort Necessity and at Braddock’s defeat; was commissioner from Virginia to conclude the treaty with the Six Nations at Fort Stanwix (1768); was a member of the Virginia House of Burgesses for several years; served as a brigadier general in the War of Independence; and in 1800 was ordered by Lord Lewis to retire to Gwynn’s Island, in Chesapeake Bay, where he had taken refuge.

2 Cornstalk and his son were killed within the fort at Point Pleasant in November 1777 by Virginia soldiers (contrary to the protests of their commanding officer, who thus avenged the death of a comrade. He was at the time warning the garrison of his inability to hold the Shawnees to the terms of the treaty of 1774. There is a granite monument (erected in 1899) over his grave in the yard of the house.

3 Various American writers have asserted that Lord Dunmore incited the Indians to attack the frontier in order to divert the colonists from their own work. The British, however, regarded the Indians as the only important agents in their commanding officer, who thus avenged the death of a comrade. He was at the time warning the garrison of his inability to hold the Shawnees to the terms of the treaty of 1774. There is a granite monument (erected in 1899) over his grave in the yard of the house.

present site of Point Pleasant; the survey of this grant was made by George Washington. After the battle General Lewis sent a detachment to build a fort (called Fort Blair) here; in 1776 Fort Randolph (abolished in 1779) was erected on the same site, and in 1785 (from which year the permanent settlement of the town may be dated) a third fort was built here. Daniel Boone lived here from 1788 until about 1799. In 1794 the village of Point Pleasant was platted; it was incorporated as a town in 1833. A granite monument (86 ft. high) commemorating the battle was unveiled on the 10th of October 1899.

**POISON.** An exact definition of the word "poison" (derived through Fr. from Lat. *poison, poisenem,* a drink; i.e. a deadly draught) is by no means easy. There is no legal definition of what constitutes a poison, and the definitions usually proposed are apt to include either too much or too little. Generally, a poison may be defined to be a substance having an inherent deleterious property, rendering it capable of destroying life by whatever avenue it is taken into the system; or it is a substance which when introduced into the system, or applied externally, injures health or destroys life irrespective of mechanical means or direct thermal changes. In popular language a poison is a substance capable of destroying life when taken in small quantity; but a substance which destroys life by mechanical means as, e.g. powdered glass, is not, strictly speaking, a poison.

The subject of toxicology forms one of the most important branches of medical jurisprudence (q.v.). The medical jurist should be familiar with the nature and actions of poisons, the symptoms which they produce, the circumstances which modify their working, the pathological results of their action, and the methods of combating these.

**Action of Poisons.**—Poisons may exert a twofold action. This may be either local, or remote, or both local and remote. The local action of a poison is usually one of corrosion, inflammation, or a direct effect upon the sensory or motor nerves. The remote actions of poisons are usually of a specific character, though some writers group the remote effects of poisons under two heads, and speak of the common and the specific remote effects of a poison. The local action of a poison of the corrosive class is usually so well marked and obvious that the fact of the administration of a poison of this class is generally unmistakable. The same may be said, in a less degree, of the irritant poisons, especially the mineral irritants; but here the symptoms are sometimes of a secondary nature, i.e. such symptoms as are due to the local irritation of the site of the poison, or to the extra-relief of irritation. It is manifest that the nature of the poison must be known to the medical jurist, who has been administered or taken will thus be suggested to his mind by the observation of the symptoms; and not infrequently the specific poison taken will be suspected. It is almost universally admitted that absorption of a poison is necessary for the production of its specific remote effects, and the old notion that a poison may kill, by its action through the nervous system, without absorption is abandoned.

**Modifying Circumstances.**—The ordinary action of a poison may be greatly modified by the largeness of the dose, by the state of aggregation, admixture, or of chemical combination of the poison, by the part or membrane to which it is applied, and by the condition of the patient. Thus, for example, opium may be a medicine or a poison, according to the dose in which it is given; and a dose of the drug which may be beneficial to an adult in certain states of the system may be fatal to a child, or to an adult when suffering from some forms of disease. All barium salts, again, are poisonous, except the quite insoluble sulphate. The simple cyanides, and many double cyanides, are highly poisonous; but yellow prussiate of potash, which is a double cyanide of iron and potassium, is almost without action upon the system. The part or tissue to which a poison is applied greatly affects the activity of a poison, owing to the varying rapidity with which absorption takes place through the cutaneous, mucous and serous surfaces, and by the other tissues of the body. Curare, an arrow poison, may be swallowed in considerable quantity without appreciable result, whilst a minute quantity of the same substance introduced into a wound is speedily fatal. Idiosyncrasy has an important bearing in toxicology. Pork, mutton, certain kinds of fish, more especially shell-fish so-called, and mushrooms have each produced all the symptoms of violent irritant poisoning, whilst other persons who have partaken of the same food at the same time have experienced no ill effects. Some persons are stated, on good authority, to be capable of taking with impunity such poisons as opium, corrosive sublimate, or arsenic, in enormous doses—and this irrespective of habit, which is known to have such an influence in modifying the effects of some poisons, notably the narcotics. A tolerance of poisons is sometimes engendered by disease, so that a poison may fail to produce its customary effect. Thus, opium is tolerated in large quantities in tetanus and in delirium tremens; and mercurial compounds may in some febrile affections fail to produce the usual constitutional effects of the metal. On the other hand, diseases which impede the elimination of a poison may intensify its effects.

The evidence that a poison has been administered is based upon the symptoms produced, on the appearances met with in the body after death, on the analysis of articles of food and drink, of excreta and ejecta, and of the organs of the body after death, and on physiological experiments made with substances extracted from the same articles. These physiological experiments are usually made upon animals, but in some cases, as for instance when aconite has to be searched for, the physiological experiments must be made also upon the human subject. The evidence obtained from one or more of these sources, as compared with the properties or effect of various known poisons, will enable the medical jurist to form an opinion as to the administration or non-administration of a poison.

The symptoms exhibited by the patient during life rarely fail to afford some clue to the poison taken. Persons may, however, be found dead of whose history nothing can be learned. Here post mortem appearances, chemical analysis, and, it may be, physiological experiments, are all-important for the elucidation of the nature of the poison.

Poisoning may be *acute* or *chronic.* The general conditions which should arouse a suspicion of acute poisoning are the sudden onset of serious and increasingly alarming symptoms in a person previously in good health, especially if there be pain in the region of the throat; and a history of the swallowing of the vital poisons, a cadaveric aspect, and speedy death. In all such cases the aid of the analytical chemist must be called in either to confirm well-founded or to rebut ill-founded suspicions.

The mode of treatment to be adopted in the case of poisoned persons varies greatly according to the nature of the poison. The first indication, when the poison has been swallowed, is to evacuate the stomach; and this may usually be done by means of the stomach-pump when the poison is not of the corrosive class; or the stomach may be gently washed out by means of a funnel and flexible siphon-tube. In many cases emetics are valuable. Antidotes and counter-poisons may then be given. The former are such substances as chalk to neutralize the mineral acids and oxalic acid; the latter have a physiological counter-action, and are such as atropine, which is a counter-poison to morphia. These may usually be administered most effectively by hypodermic injection. The stomach may to a certain degree be protected from the injurious effects of irritants by the administration of mucilaginous drinks; alkaloïds may be rendered sparingly soluble by means of astringent substances containing tannin; and pain may be relieved by means of opium, unless contra-indicated by the nature of the poison.

The effects of the convulsant poisons, such as strychnine, may be combated by means of the inhalation of chloroform. The classification of poisons is a matter of difficulty. Various...
attempts have been made to classify them scientifically, but with no signal success; and perhaps the best system is that which groups the various poisons according to the more obvious symptoms which they produce. A more intimate action of poisons is still too imperfect to admit of any useful classification according to the manner in which they specifically affect the vital organs. Poisons may be indicated as classified by

(1) Corrosives, (2) Irritants, (3) Neurotics, and (4) Gaseous Poisons.

1. Corrosives.
The typical member of this class is corrosive sublimate, the soluble chloride of mercury. In it are included also the concentric or hydrochloric acids, hydrobromic acid, oxalic acid; the alkalies (potash, soda, and ammonia) and their carbonates; acid, alkaline, and corrosive salts of the metals (such as bisulphate of potash, alum, butter of antimony and nitrate of silver); also carbonic acid.

The symptoms produced by the mineral acids and the alkalies are almost altogether referable to local action; but some corrosive poisons, such as carbic acid, produce, besides a local action, remote and specific constitutional effects. The symptoms of corrosive poisoning are marked and unmistakable, except in infants. Immediately swallowing the corrosive substance, an acid, caustic or metallic burning sensation is experienced in the mouth, fauces, gullet, and stomach. In its passage through the stomach, the whole belly; as a rule vomiting speedily follows. In the case of the mineral acids, and in oxalic acid poisoning, the vomit is so acid that if it falls upon a marble or concrete floor effervescence ensues. Sometimes the evacuations of the stomach or bowels, contain blood, and even fragments of the corroded walls of the alimentary canal. The belly becomes distended with gas; the bowels are perpetually relaxed. The mouth is found to be corroded. Death usually occurs within the last few days; or, if the patient survives, he or she may perish miserably, months after the poison was taken, through starvation consequent upon the general contraction of the gullet, brought about by its corrosion and subsequent healing.

The treatment of corrosive poisoning consists in very gently emptying and washing out the stomach by means of a soft siphon-tube. No stomach pump can be used with safety in consequence of the weakening of the walls of the stomach by corrosion. Demulcents and opiates may be subsequently administered. After death from corrosive poisoning the walls of the stomach are found corroded and perforated.

1. Corrosive Sublimate.—Here all the signs and symptoms of corrosive poisoning are produced in their severest form. In an hour or two of this poison may prove fatal. Fortunately there is an efficient antidote in white of egg, the albumen of which, if administered at once, renders the salt insoluble. The eggs should be divested of their yolks, beaten up with water, and given promptly, repeatedly, and up to 15 or 30 minutes after the last dose. Poisoning by corrosive sublimate may be followed by the specific toxic effects of mercury, such as salivation and tremor.

Workers in mercury, such as water-gilders, looking-glass makers, and in the manufacture of blue vitriol, asphaltum powders, are apt to contract a peculiar form of shaking palsy, known as "the trembles," or mercurial tremor. This disease affects most frequently those who are exposed to mercuorial fumes. The victim is affected with tremors when an endeavour is made to exert the muscles, so that he is unable, for instance, to convey a glass of water to the lips steadily, and when he walks he breaks into a dancing trot. The treatment consists in removal from the mercuorial atmosphere, baths, fresh air, and abstention from the administration of alcohol.

2. Mineral Acids.—These are oil of vitriol or sulphuric acid, aqua fortis or nitric acid, and spirit of salt or hydrochloric (muriatic) acid. These, when taken in a concentrated form, produce well-marked and characteristic symptoms of corrosion. When they are diluted, the symptoms are those of an irritant poison. Nitric acid stains the mouth and skin of a yellow colour. The treatment consists in the administration of the alkalies or other carbonates, chalk, whiting, or even uncoloured plaster scraped off the walls or ceiling, with the view of neutralizing the acid.

3. Oxalic Acid is a vegetable acid. When taken in the state of corrosive sublimate, it acts as a corrosive, but when diluted it only affects the mucous membrane of the respiratory tract. It is a depressant of the heart, and a source of excitement to the heart. A patient subjected to an oxalic acid fumes is sometimes thrown into a state of collapse, collapse, and collapse; and as the heart beats slower and thinner, and fails, a small pulse and failure of the heart's power, poisoning by oxalic acid is almost certain. The treatment consists in promptly administering an emetic, followed by chalk, whiting, or any sub- stantial food. When they are diluted, the symptoms are those of a corrosive, but are much more valueless, for the alkaline oxalates are almost as poisonous as oxalic acid itself.

4. The Alkalies.—Caustic potash and caustic soda produce symptoms resembling those of the mineral acids, except that purging is a usual accompaniment.

5. Carboxylic acid when taken in the form of a concentrated liquid acts as a corrosive, causing whitening and shrinking of all the animal membranes with which it comes in contact. The patient, however, becomes speedily comatose, the poison acting profoundly on the central system. A free rendering of the blood is rare. A dark green urine—is commonly observed after the administration of this poison. Saccharated lime-water, diluted and drunk freely, and a solution of sulphate of soda are perhaps the most useful remedies.

2. Irritant Poisons.

Irritant poisons are of two classes—metallic irritants and vegetable and animal irritants, these latter being for convenience grouped under the latter title. As irritants they are perhaps the least dangerous, the irritant symptoms being usually accompanied by well-marked effects upon the nervous system. An irritant is a substance which possibly affects the skin, or some other part of the body, without causing any of the effects produced by the metallic irritants. Other irritants are the moderately diluted acids, many metallic salts, such as those of antimony, lead, copper, and zinc; vegetable juices, as vinegar, tannin, and croton oil are good examples of vegetable irritants; and cantharides of animal irritants. Animal and vegetable food when decomposed, or infected with certain organisms known as bacteria, may produce violent irritant symptoms. The symptoms produced by irritant poisons are usually more slow in their development than where a corrosive has been administered. Usually, after an interval, greater or less according to the specific nature of the irritant present, an irritant poison may, if the irritant is sufficiently powerful, with a sense of constriction of the parts, and followed by burning pain in the region of the stomach. This is increased, and not alleviated, by pressure, a mark which serves to distinguish the irritant poison from the corrosive. The irritant poison is, however, a most deleterious and rapid poison. Should the poison not be speedily eliminated in the vomited and excreted form, the dangers over set in, followed by collapse; and death may ensue in a few hours.

There is danger of confounding irritant poisoning with some forms of natural disease, such as gastritis and gastric ulcer, colic, peritonitis, cholera, and rupture of the intestines.

1. Arsenic is a specific irritant poison. Almost all the compounds of this metal are poisonous. The term "arsenic" is, however, somewhat loosely used. By arsenic is usually meant the element itself, but to its low oxide, arsenious oxide, which is also known as white arsenic. By whatever channel arsenic is introduced into the system, it invariably affects specifically the stomach and intestines, causing contraction of the walls of the alimentary canal, and evacuation of the bowels. The symptoms from the ingestion of chemical poisons are the taking of white arsenic, which causes acute poisoning, and the inhalation of dust from arsenical wall-paper and textile fabrics, whereby a chronic form of poisoning is induced.

The symptoms and treatment of arsenical poisoning are described under Arsenic (q.v.). Arsenic-eating, or the ability of some persons to take relatively large quantities of arsenic habitually, is a well-established fact. The cause of this singular immunity from the ordinary results of arsenic is unknown.

2. Lead.—The salts of lead, more especially the acetate (sugar of lead), the nitrate, and lead bichromate, are frequently taken by emetics, and, though occasionally death ensues, recovery is the rule. Yellow, or lead chromate, is a powerful irritant poison. All chromates are, indeed, irritant poisons. (See Lead Poisoning.)

3. Potassium nitrate is blue vitriol (the sulphate) and verdigris (subcarbonate and subacetate), are emetic and irritant salts. Their emetic effects usually, but not invariably, secure their prompt rejection by the stomach. Occasionally fatal effects have resulted from their administration. Copper becomes accidentally mixed with articles of dietary in a variety of modes. It is also used for improving the colour of preserved fruits and vegetables. Its deleterious properties when thus used in minute quantities have been asserted with much heat and at times of great length. There is, however, a large body of evidence in favour of the at all events occasional poisonous effects of minute quantities of copper.

4. Zinc salts and barium salts, except the quite insoluble barium sulphate, are irritant poisons; and barium compounds act also upon the central nervous system.

5. Chromates, e.g. bichromate of potash, are violent irritants. Chromium metal, or lead chromate, has already been mentioned.

6. Phosphorus. Of the chief forms of phosphorus—the yellow or ordinary and the red or amorphous—the former only is poisonous. Rarely there is met with a chronic form of poisoning caused by the inhalation of phosphorus vapours. Its special characteristic is a peculiar necrosis or death of the bony structure of the lower jaw. Acute phosphorus poisoning is more common. Phosphorus is used for setting of the gunpowder, and for the manufacture of phospho-vapours. (See Phosphorus and Match.)

7. Vegetable Irritants.—These produce drastic purgative effects. Frequently the nature of the illness may be ascertained by the discovery of portions of the vegetable substance recognizable by the microscope—in the matters ejected by the patient.
8. Cantharides.—The administration of cantharides (g.a.) is followed by vomiting, purging, stranguary, or even entire inability to micturate. In some cases the skin becomes irritated, and blistering of the lip or any tender mucous surface to which it is applied. Demulcent remedies, with opiate emenata and injections, afford the best relief by way of treatment.

1. Prussic or Hydrocyanic Acid.—Hydrocyanic acid is one of the best known of man-made poisons. In the pure state it is said to kill with lightning-like rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeial acid, containing 0.5% and the industrial acid, containing 2% of cyanogen. Less than a teaspoonful of the 2% acid has caused death. Given in fatal doses, the symptoms of prussic-acid poisoning set in with great rapidity; and, as a consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before alarming symptoms are developed. There is first a very brief stage of difficult breathing, and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely-dilated pupils of the eye, the patient is theoretic paralyzed, with a rapid and shallow breathing. The rhythm of the respiratory movements is disturbed, and the countenance becomes of a bluish cast. The patient now sinks to the ground with complete loss of muscular power; and the third or aspiratory stage is characterized by a total cessation of all muscular actions, loss of pulse, and paralysis of motion. Death is frequently preceded by muscular spasms. The fourouyant character of the illness, and the speedy death of the patient, coupled with the suddenness of the attack, the ready access to the breathing, and the body, seldom leave any doubt as to the nature of the case. The treatment consists in inhalation of fumes of strong ammonia, the application of warm and cold water alternately, friction of the limbs, and artificial respiration. The subcutaneous injection of atropine, which acts as a cardiac stimulant, may prove serviceable.

Other soluble cyanides, more especially cyanide of potassium, a salt of warm and cold water alternately, friction of the limbs, and artificial respiration. The subcutaneous injection of atropine, which acts as a cardiac stimulant, may prove serviceable.

2. Opium.—In consequence of the extent to which opium, its preparations, and its active alkaloid morphine are used for the relief of all kinds of pain, there is a frequent occurrence of accidental or suicidal poisoning by means of the drug. Opium is largely used by soldiers in the fields of battle, and by sailors at sea. Opium is also part of many of our drug prescriptions, and it is used extensively in many processes of manufacture, and especially in the manufacture of carbonate of soda from common salt by Le Blanc's process, for the purging of earthenware, and in the manufacture of artificial manure.

3. Sulphuric Acid Gas.—The gas given off by burning sulphur is most suffocating and irritating. Its inhalation, even in a highly diluted state, may cause speedy death from spasmodic closure of the glottis.

4. Nitrous vapours, or gaseous oxides of nitrogen (except nitrous oxide), are given off from galvanic batteries excited by nitric acid; also from certain copper batteries, which have been allowed to remain dilute, little immediate irritation, but are exceedingly dangerous, setting up extensive and fatal inflammation of the lungs.

5. Ammonia gas is highly irritant, but does not often prove fatal. In cases of over-exposure, the inhalation of a strong ammonia or alkaline vapour for a few minutes, will relieve the symptoms completely.

6. Carbon dioxide gas is heavier than atmospheric air, and is totally irrespirable when pure, and is fatal when present in large quantities in respired air. It is given off from burning fuel, accumulates in pits and wells as choke-damp, and constitutes the deadly after-damp of coal-mines. It is also formed during alcoholic fermentation, and hence accumulates in partially filled vats in which fermented liquors are stored. When it is breathed in a concentrated state, it produces asphyxia. Persons descending into mines for which this gas sinks downward, without proper respirators, before they can be removed from the vitiated atmosphere. In these cases there is true asphyxia; but carbonic acid is also a narcotic gas. Death is usually caused by the inhalation of a large quantity, but not long enough to produce fatal results, are affected with stertorous breathing, oppression, flushed face, prominent eyes, swollen tongue and feeble pulse. The proper treatment is removal from the foul atmosphere, alternate cold and hot douches to the chest, friction of the limbs and trunk, and artificial respiration. When animation is restored the patient should be put to bed and kept quiet, but should be carefully watched in case of relapse.

7. Carbon monoxide gas is given off by burning charcoal and other forms of fuel, mixed with carbonic acid. The poisonous effects of charcoal fumes are perhaps due rather to the more poisonous carbonic oxide than to the less poisonous carbonic acid. An atmosphere of charcoal fumes cannot be endured for more than a few minutes, it is fatal if breathed for more than a few minutes. Carbonic oxide forms with haemoglobin, the red pigment of the blood, a bright scarlet compound. The compound is very stable, and the oxide cannot be displaced by atmospheric oxygen. Hence the blood after death from the inhalation of carbonic oxide is of a bright arterial hue, which it retains on exposure to air.

8. Coal-gas acts as an asphyxian and narcotic. The appearance of gas in the chamber after the gas met has been still more especially the fluid state of the blood—these are similar to those observed after death from carbonic oxide gas, which is a constituent of coal-gas, and to which the chief effect of the gas may be traced.

9. Sulphured hydrogen gas is highly poisonous by whatever channel it gains access to the body. In a concentrated form it produces almost instant death from asphyxia. Even in a diluted form it is highly poisonous, and may pass into insensibility with lividity and feeble respiration.

The skin is cold and clammy, or bathed in perspiration. The red blood corpuscles are disintegrated. The treatment consists in removal from the contaminated atmosphere, friction to the surface of large doses they produce violent vomiting, as a rule, more or less paralyzation of motion and sensation, and great depression of the heart, sometimes with rapidity; but the skin remains unaffected till almost the last. The treatment consists in the hypodermic injection of digitalis, which is a counter-poison in its action upon the heart. The root ofaconite has been eaten in mistake for apple in Great Britain, and has caused fatalities. It is said to be frequently met with in Great Britain, and has caused fatalities.
of the body, warmth, and the administration of stimulants. The inhalation of chlorine gas has been recommended on chemical grounds; but it must be remembered that chlorine itself is poisonous.

10. Anaesthetics.—Nitrous oxide, or laughing gas, and the gases or vapours of other anaesthetic substances, such as chloroform, may, if improperly administered, produce death by asphyxia, and perhaps otherwise. Obviously, as a rule, medical assistance is at hand. The treatment consists in artificial respiration, and the use of galvanic current.

11. Vapours of Hydrocarbons.—The volatile vapours of the natural hydrocarbons known as benzolone, petroleum, &c., are poisonous when inhaled by the lungs. poisoning.

POISSON, SIMÉON DENIS (1781-1840), French mathematician, was born at Pithiviers in the department of Loiret, on the 21st of June 1781. His father, Siméon Poisson, served as a common soldier in the Hanoverian wars; but, disgusted by the ill-treatment he received from his parochian officers, he deserted. About the time of the birth of his son, Siméon Denis, he occupied a small administrative post at Pithiviers, and seems to have been at the head of the local government of the place during the revolutionary period. Poisson was first sent to an uncle, a surgeon at Fontainebleau, and began to take lessons in bleeding and blistering, but made little progress. Having given promise of mathematical talent he was sent to the École Centrale of Fontainebleau, and was fortunate in having a kind and sympathetic master, who, though he was Poisson's pupil, was becoming his master, devoted himself to the study of higher mathematics in order to follow and appreciate him, and predicted his future fame by the punning quotation from LaFontaine:—

"Petit Poisson deviendra grand.
Pourvu que Dieu lui prête vie."

In 1798 he entered the École Polytechnique at Paris as first in his year, and immediately began to attract the notice of the professors of the school, who left him free to follow the studies of his predilection. In 1800, less than two years after his entry, he published two memoirs, one on É. Bézout's method of elimination, the other on the number of integrals of an equation of finite differences. The latter of these memoirs was examined by S. F. Lacroix and A. M. Legendre, who recommended that it should be published in the Recueil des savants étrangers, an unparalleled honour for a youth of eighteen. This success at once procured for Poisson an entry into scientific circles. J. L. Lagrange, whose lectures on the theory of functions he attended at the École Polytechnique, early recognized his talent, and became his friend; while P. S. Laplace, in whose footsteps Poisson followed, regarded him almost as his son. The rest of his career, till his death on the 23rd of April 1840, was almost entirely occupied in the composition and publication of his many works. He was discharging the duties of the numerous educational offices to which he was successively appointed. Immediately after finishing his course at the École Polytechnique he was appointed répétiteur there, an office which he had discharged as an amateur while still a pupil in the school; for it had been the custom of his comrades often to resort to his room after an unusually difficult lecture to hear him repeat and explain it. He was made professeur suppléant in 1802, and full professor in succession to J. Fourier in 1806. In 1808 he became astronomer to the Bureau des Longitudes; and when the Faculté des Sciences was instituted in 1809 he was appointed professeur de la mécanique rationelle. He further became member of the Institute in 1812, examiner at the military school at St Cyr in 1815, leaving examiner at the École Polytechnique in 1816, councillor of the university in 1820, and geometer to the Bureau des Longitudes in succession to P. S. Laplace in 1827. His father, whose early experiences led him to hate aristocrats, bred him in the stern creed of the first republic. Throughout the empire Poisson faithfully adhered to the family principles, and refused to worship Napoleon. When the Bourbons were restored, his hatred against Napoleon led him to become a Legitimist—a conclusion which says more for the simplicity of his character than for the strength or logic of his political creed. He was faithful to the Bourbons during the Hundred Days; in fact, was with difficulty dissuaded from volunteering to fight in their cause. After the second restoration his fidelity was recognized by his elevation to the dignity of baron in 1825; but he never either took out his diploma or used the title. The revolution of July 1830 threatened him with the loss of all his honours; but this disgrace to the government of Louis Philippe was adroitly averted by F. Arago, who, while his "revocation" was being plotted by the council of ministers, procured him an invitation to dine at the Palais Royale, where he was openly and effusively received by the citizen king, who "remembered him. After this, of course, his degradation was impossible, and seven years later he was made a peer of France, not for political reason, but because he had been one of the Frenchmen who had contributed most to the advancement of science.

As a teacher of mathematics Poisson is said to have been more than ordinarily successful, as might have been expected from his early promise as a répétiteur at the École Polytechnique. As a scientific worker his activity has rarely if ever been equaled. Notwithstanding his many official duties, he found time to publish more than three hundred works, several of them extensive treatises, and many of them memoirs dealing with the most abstruse branches of pure and applied mathematics. There are two remarks of his, or perhaps two versions of the same remark, that explain how he accomplished so much: one, "La vie est une succession de miracle et de mathématiques," and the other, "La vie c'est le travail."

A list of Poisson's works, drawn up by himself, is given at the end of Arago's biography. A lengthened analysis of them would be out of place here, and all that is possible is a brief mention of the more important. There are few branches of mathematics to which he did not contribute something, but it was in the application of mathematics to physical subjects that his greatest services to science were performed. Perhaps the most original, and certainly the most permanent in their influence, were his memoirs on the theory of electricity and magnetism, which virtually created a new branch of mathematical physics. Next (perhaps in the opinion of some first) in importance stand the memoirs on celestial mechanics, in which he proved himself a worthy successor to L. Euler. The last period of his life was devoted to the inequalities séculaires of the mouvements de la lune, and to the solution of a large number of problems of the theory of perturbations. In this last work he showed that the result could be extended to a second approximation, and thus made an important advance in the planetary theory. The memoir to which he devoted his life in the last years of his inactivity, to compose in his old age one of the greatest of his memoirs, viz. That. Sur la théorie des variations des éléments des orbites de la lune (1824); this is a treatise on the artificial elongations of the moon's orbit. So highly did he think of Poisson's memoir that he made a copy of it with his own hand, which was found among his papers after his death. Poisson made important contributions to the theory of attraction. His well-known correction of Laplace's partial differential equation for the potential was first published in the Bulletin de la société philomatique (1813). His two most important memoirs on the subject are: Sur l'attraction des sphéroïdes (Proc. d. acad., 1820), and "Sur l'attraction d'un ellipsoide homogène" (Mem. d. acad., 1835). In concluding our selection from his physical memoirs we may mention his memoir on the theory of waves (Mem. d. acad., 1825).

It is impossible to give a complete account of Poisson's mathematical works, as these were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of L. Dirichlet and B. Riemann on the same subject; these are to be found in the Journal of the École Polytechnique from 1813 to 1823, and in the Mémoires de l'académie for 1823. In addition we may also mention his essay on the calculus of variations (Mem. d. acad., 1833), and his memoirs on the probability of the mean results of observations (Conseils, 17 temps, 1826, &c.). Besides his many memoirs Poisson published a number of treatises, most of which were intended to form part of a great work on mathematical physics, which was not live, as he mentioned his Traité de mécanique (2 vols., 8vo, 1831 and 1833), which was long a standard work; Théorie nouvelle de l'action capillaire (4to, 1831); Théorie mathématique de la chaleur (4to, 1835); and a treatise on the study of the phenomena of electrical insulation. In 1833, Poisson was called to a judicial position as a conseiller des jugements en matières criminelles, &c. (4to, 1837), all published at Paris. See F. Arago, Biographie de Poisson, read before the Académie des Sciences on the 16th of December 1850.
POISSY—POITIERS

POISSY, a town of northern France, in the department of Seine-et-Oise, 17 m. W.N.W. of Paris, on the railway from Paris to Rouen. Pop. (1906), 6043. The church, supposed to have been built in the first half of the 12th century, and entirely restored under the direction of Viollet le Duc, is of special architectural interest, as affording one of the earliest and best examples of transition from the Romanesque to the Pointed style. The bridge of Poissy, a very ancient foundation, has been widened and modernized; of the mills which formerly bordered it one was known as Queen Blanche's. A statue of the painter J. L. E. Meissonier was erected in 1864, close to his house. Poissy supplied butchers' meat to Paris during six centuries, but in 1867 the market was removed to the metropolis. A handsome fountain stands in the old market-place. Distilling and the manufacture of chairs and flour-milling equipment are carried on and ragstone is quarried.

Poissy, the ancient Pincæcum, was the capital of the county of the Carnutes. In the time of Charlemagne it had a royal palace, where during the 9th century four national assemblies were held. Later it became a favourite residence of Blanche of Castille, and her son, afterwards St Louis, is supposed to have been born there. Philip the Fair gave the castle to the Dominicans, by whom it was completely transformed, and it was in the refectory of the abbey that the famous conference (see below) between the Roman Catholics and Protestants took place in 1561.

POITIERS. COLLOQUIY OF, a conference held in 1562 with the object of effecting a reconciliation between the Catholics and Protestants of France. It was initiated by Queen Catherine de' Medici, regent during the minority of her son Charles IX. In the policy of which it was the outcome she enjoyed the support of the Chancellor Michel de l'Hôpital and the lieutenant-general of the kingdom, Anthony of Navarre; while on the other hand the heads of the Catholic party had attempted to frustrate any form of negotiation. Theodore Beza from Geneva and Peter Martyr Vermigli from Zürich appeared at the colloquy; the German theologians to whom invitations had been despatched only arrived in Paris after the discussion was broken off. The conference was opened on the 9th of September in the refectory of the convent of Poissy, the king himself being present. The spokesman of the Reformed Church was Beza, who, in the first session, gave a lengthy exposition of its tenets, but excited such repugnance by his pronouncements on the Communion that he was interrupted by Cardinal Tournon. In the second session (Sept. 16) he was answered by the cardinal of Lorraine, who discharged his task with skill and moderation. On the motion, however, of Ippolito d'Este, the papal legate, exception was taken to the further conduct of the negotiations in full concele; and a committee of twenty-four representatives, twelve from each party, was appointed—ostensibly to facilitate a satisfactory decision. On the Catholic side, as was speedily demonstrated, there existed no sort of tendency to conciliation; on the contrary, the cardinal of Lorraine, by his question whether the Calvinists were prepared to sign the Confession of Augsburg, attempted to sow dissension between them and the Lutheran Protestants of Germany, on whose continued support they calculated. The Catholic delegates, moreover, discovered a powerful auxiliary when Lainez, the general of the Jesuit order, which had been admitted into France a short time previously, entered the debate; and the acrimony with which he opposed the Protes-
tants was of material service in clarifying the situation. Still a further reduction was made in the number of members, and a small residuum consisting of five Catholics and five Protestants undertook the task of revising the 12th formula, on which the churches might unite with regard to the question of the Communion. Their difficult labours even seemed on the point of success when the assemblage of prelates refused assent, and the conference broke up on the 9th of October—a result which barred the way to a pacific understanding with the Huguenots.

POITIERS, a town of western France, formerly the capital of Poitou, and now the chief town of the department of Vienne, 61 m. S.S.W. of Tours on the railway to Bordeaux. Pop. (1906), 59,916; commune 20,302. Poitiers is situated at the junction of the Boivre with the Clain (a tributary of the Loire by the Vienne), and occupies the slopes and summit of a plateau which rises 130 ft. above the level of the streams by which it is surrounded on three sides. The town is picturesque; and its streets are interesting for their remains of ancient architecture, especially of the Romanesque period, and the memories of great historical events. Blossac park, named after the intendant of the "generality" of Poitiers (1751-1786), and situated on the south side of the town, and the botanical garden on the north-east, are the two principal promenades. Till 1857 Poitiers contained the ruins of a Roman amphitheatre more extensive than that of Nîmes; remains of Roman buildings, constructed in the 1st and demolished in the 3rd century, were laid bare in 1877; and in 1879 a burial-place and the tombs of a number of Christian martyrs were discovered on the heights to the south-east—the names of some of the Christians being preserved in paintings and inscriptions. Not far from these tombs is a huge dolmen (the 'Pierre Levée'), 23 ft. long, 16 ft. broad and 6 or 7 ft. high, around which used to be held the great fair of St Luke.

The cathedral of St Peter, begun in 1162 by Henry II. of England and Eleanor of Guîenne on the ruins of a Roman basilica, and well advanced by the end of the 12th century, is a building in the Romanesque and Early Gothic style, the latter predominating. It consists of three naves almost equal in height and width, both of which decrease towards the west, thus enhancing the perspective. Its length is 508 ft., and the keystone of the central vaulted roof is 80 ft. above the pavement. There is no apse, and the exterior generally has a heavy appearance. The principal front, the width of which is excessive in proportion to its height, has unfinished side-towers 105 and 110 ft. in height, begun in the 13th century. Most of the windows of the choir and the transepts preserve their stained glass of the 12th and 13th centuries; the end window, which is certainly the first in the order of time, contains the figures of Henry II. and Eleanor. The choir stalls, carved between 1235 and 1255, are among the oldest in France. The church of St Jean near the cathedral is the most ancient Christian monument in the country. Built as a baptistery in the first half of the 4th century, it was enlarged in the 7th century, since when it has suffered little structural alteration. It contains frescoes of the 12th century and a collection of tombs of the Merovingian period. The church of St Hilaire was erected at the close of the 4th century over the tomb of the celebrated bishop. At first an oratory, it was rebuilt on a larger scale by Clovis, and afterwards became, in the roth, 11th and 12th centuries, a sumptuous collegiate church, of which the nave was flanked by triple aisles and surmounted by six cupolas. Great damage was done to it in the Wars of Religion and the French Revolution, and the façade was entirely rebuilt in the 19th century. The confes-
sional or oratory under the choir contains the relics of St Hilary and a Christian sarcophagus of the 4th century. The church of St Radegonde, a great resort of pilgrims, commemorates the consort of Clotaire (d. 537), and preserves in its crypt the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross, and two others reputed to be those of St Agnes and St Disciola. The choir and tower above the entrance are of the 11th century, while the nave (late 12th century) is in the Angevin style. In a recess in the nave known as the Chapelle du Pas de la Jatte there is a frontal which tradition attributes to St Thomas of Canterbury, which appeared in a vision to St Radegonde. Notre-Dame la Grande, which dates from the close of the 11th century, and represents a collegiate church of one or two hundred years older, has a sculptured Romanesque façade rivalled in richness only by that of St Pierre of Angoulême. The first stone of the church of Montierneuf (Monasterium Novum) was laid in 1077 by William VI., duke of Aquitaine and count of Poitiers, who is buried within its walls; and the choir (in the 13th century
modified by the erection of a "lantern") was solemnly consecrated by Urban II. in 1056. Mutilated about 1640 and during the Revolution, the building was partly restored between 1850 and 1860. The tower of St Porchaire, a precious remnant of 11th-century architecture, was restored in the 19th century under the auspices of the well-known Société des antiquaires de l'Ouest.

Among the secular buildings the first place belongs to the law courts, formerly the palace of the dukes of Aquitaine and counts of Poitiers, and rebuilt between the 12th and the 15th century. The Salle des Pas Perdus forms a fine nave 160 ft. long by 56 ft. wide, with a vaulted wooden roof. The southern wall is the work of duke Jean de Berry (d. 1416), brother of Charles V.; above its three vast fireplaces are mullioned windows filled with stained glass. The Maubergeon tower attached to the palace by the same duke represented the feudal centre of all the lordships of the countship of Poitiers. The house known as the préséduit or provost's mansion, built about 1500, has a fine façade flanked by turrets, and there are other houses of the 15th, 16th and 17th centuries. In the Hôtel de Ville, erected between 1860 and 1876, are museums of natural history and art. The one of the Tournelles, which occupies the chapel and the great hall of the old university, adjoining the old Hôtel de Ville; it is a valuable collection comprising Roman antiquities, Merovingian sculptures, medals, a fine Renaissance fireplace, &c. The building devoted to the faculties also contains the library. The municipal records are very rich in charters of Eleanor of Guienne, Philip Augustus, Alphonse of Poitiers, &c.

Poitiers is the seat of a bishop, a prefect, a court of appeal and a court of assizes, and centre of an educational division (académie), and has tribunals of first instance and of commerce, a board of trade arbitration, a chamber of commerce and a branch of the Bank of France. Its educational institutions comprise a university with faculties of law, science and letters, and a preparatory school of medicine and pharmacy, a school of theology, training colleges for both sexes, a lycée for boys and a school of fine art. Trade is in farm produce, wine, cattle, wool, honey, goose-quills and leather. The industries include the preparation of goose-skins, printing, tanning, and the manufacture of brushes, paint and candles.

Poitiers, called Limousin at the time of the Roman Conquest, afterwards took the name of its Gallic founders, the Pictones or Pictavi. Christianity was introduced in the 3rd century, and the first bishop of Poitiers, from 350 to 367, was St Hilarius. Fifty years later the city had fallen into the hands of the Arian Visigoths, and became one of the principal residences of their kings. Alaric II., one of their number, was defeated by Clovis at Vouillé, not far from Poitiers, in 507, and the town became a part of the Frankish dominion. This was the first occasion on which the peoples of northern and southern Gaul met in conflict in the neighbourhood of the town which was destined to see them so frequently join battle. By his victory in 732 over the Mahommedans at Moussais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Eleanor of Guienne frequently resided in the city, which she embellished and fortified, and in 1199 entrusted with communal rights. Alphonse of Poitiers, in his capacity as controller of the city, which in the hands of the Aquitaine Palais de Justice, received the homage of his numerous vassals. After the battle of Poitiers in 1356 (see below), Poitou was recognized as an English possession by the treaty of Brétigny (1360); but by 1373 it was recovered by Bertrand Du Guesclin. It was at Poitiers that Charles VI. was proclaimed king (1429); and he removed thither the parlement and university of Paris, which remained in exile till the English withdrew from the capital in 1436. During this interval (1430) Joan of Arc was subjected to a formal inquest in the town. The university was founded in 1452. Calvin had numerous converts at Poitiers. Of the violent proceedings which attended the Wars of Religion the city was little spared. In 1546 it was defended by Guillaume de Duillou, comte de Lude, against Gaspard de Coligny, who after an unsuccessful bombardment retired from the siege at the end of seven weeks.

Counts of Poitiers.—In the time of Charlemagne the countship of Poitiers, which was then a part of the kingdom of Aquitaine, was represented by a certain Abbon. Renoul (Ranulph), who was created count of Poitiers by the emperor Louis the Pious in 836, was the ancestor of a family which was distinguished in the 9th and 10th centuries for its attachment to the Carolingian dynasty. One of his successors, Edble the Bastard (d. 932), took the title of duke of Aquitaine; and his descendants, who bore the hereditary name of William, retained the same title. William IV., Fièrebracq, joined Hugh Capet, his brother-in-law, in 877. William V. the Great (903-1030) was a patron of letters, and received from the Italian lords the offer of the imperial crown after the death of the emperor Henry II. in 1024. William IX. (1086-1127) went on crusade in 1100, and had violent quarrels with the Papacy. His son William X. (1127-1137) sided with the anti-pope Anacletus against Innocent II. In accordance with the dying wishes of William X. his daughter Eleanor was married in 1137 to Louis, the son of Louis VI. of France. Sole heiress of her father, she brought her husband a large dowry, comprising Poitou, Saintonge, Aunis, Aunis, Poitou, and the Duchy of Aquitaine. The title of Aquarium and Aveyron, Auvergne, Limousin, Bordeaux, Agénos and Gascony. After the dissensions between Louis VII. and Eleanor had resulted in a divorce in 1152, Eleanor married the count of Anjou, Henry Plantagenet, who became king of England as Henry II. The west of France thus passed into the hands of England, a transfer which gave rise to long wars between the two kingdoms. Philip Augustus reconquered Poitou in 1204, and the province became in succession an apanage of Alphonse, son of Louis VIII., in 1241; of Philip the Tall, son of Philip the Fair, in 1311; of John, son of Philip of Valois, in 1344; and of John, duke of Berry, son of John of Good, in 1356 and passed to the dauphins John (1410) and Charles (1417), son of Charles VI. When Charles VII. ascended the throne he finally united the countship of Poitiers to the Crown.

Battle of Poitiers.—This battle, fought on the 19th of September 1356 between the armies of King John of France and Edward the "Black Prince," was the second of the three great English victories of the Hundred Years' War. From Bordeaux the prince had led an army of his father's Guienne vassals, with which there was a force of English archers and men-at-arms, into central France and had amassed an enormous booty. King John, hitherto engaged against the army of John of Gaunt, duke of Lancaster, in Normandy, hurried south to intercept the raiding army and to bar its homeward road. The Black Prince, by forced marching, was able to slip past the French, but reaching Maupertuis, 7 m. south-east of Poitiers, with the king's army in chase, he found himself compelled to choose between fighting and abandoning his spoil. He chose the former course, in spite of the enemy's great superiority in numbers (16,000 to 6500), and in order to give his trains time to draw off took up a defensive position on the 18th of September, with a slight hollow in front and a wood behind, between the Poitiers-Bordeaux main road and the River Maussion.1 John, instead of manoeuvring to envelop the English, allowed the Cardinal Talleyrand de Périgord to attempt to negotiate a peace. This proving vain, the French army attacked without any attempt at manoeuvre or reconnaissance, and on a front so narrow that the advantage of superior numbers was forfeited. Moreover, King John ordered all but the leading line to dismount and take up a position behind a hedge (tactics suggested by the success on the defensive of the dismounted English men-at-arms at Crecy and the Scots at Bannockburn), and thus condemned the best part of his army to a fatiguing advance on foot across difficult country in full armour.

The French arbalists, who might have crushed the relatively

1 The view adopted is that of Professor Oman, Art of War, Middle Ages, p. 631.
few English archers present, were mingled with the 300 picked mounted men in first line, but, as the latter charged, their advance masked the fire of the arbalisters in the first few seconds, before leaving the other, dismounted, lines far in rear. Thus the first attack on the Black Prince returned. Poitiers therefore strengthened by trees and hedges in front of it, was promptly brought to a standstill by the arrows of the archers lining a hedge which overlooked the hollow in front; and the earl of Oxford hastily drawing out a body of archers beyond the defenders’ left, into the low-lying ground of the Maussian valley, completed their rout by firing up the hollow into their flank. But it was not so easy to deal with the second line of dismounted men-at-arms, led by the dauphin, which was the next to arrive on the French side. The hedge indeed was held, and the assailants, unable to advance beyond the hollow, gave way, but to achieve this the prince had to use all but 400 of his men. Had the third body of the French advanced with equal spirit the battle would probably have ended there and then, but the duke of Orleans, who commanded it, was so demoralized by the retirement of the dauphin’s division that he led his whole force off the field without striking a blow. Thereupon the king himself advanced furiously with the fourth and last line, and as it came on the situation of the English seemed so desperate that the prince was advised to retreat. But his determined courage was unshaken; seeing that this was the last attack he put his reserve into line, and rallying around this nucleus all men who could still fight, he prepared not only to repulse but to counter-attack the French. He despatched a small force under the Capitde Buch to ride round the flank of the enemy and to appear in their rear at the crisis of the fight. Though a medieval knight, he knew as well as Napoleon at Arcola that when the moral force of both sides has passed its culminating point even a materially insignificant threat serves to turn the balance. And so it fell out. When both lines were fighting hand-to-hand, the fifty horsemen of the Capit de Buch appeared in rear of the French. The front ranks fought on, but the rear of the French melted away rapidly, and at last only a group of the bravest, with King John and his son Philip, a boy of fourteen, in their midst, were left. This band continued their hopeless resistance for a time, but in the end they were killed or captured to a man. The rest of the French army, totally dispersed, was pursued by the victors until nightfall. Two thousand five hundred of the French, 2000 of them knights and men-at-arms, were killed, including the constable, one of the marshals, the standard-bearer and six other great lords. The prisoners included the king and his son Philip, the other marshal and 25 great lords, and 1933 knights and men-at-arms as well as 500 others.

POITOU, one of the old provinces of France, which also formed one of the great military governments of the kingdom, was bounded on the N. by Brittany, Anjou and Touraine; on the S. by Angoumois and Auin; on the E. by Touraine, Berri and Marche; and on the W. by the ocean. It was divided into Lower Poitou, which corresponded to the modern department of La Vendée, and Upper Poitou, now split into the departments of Deux-Sèvres and Vienne. The principal towns in Upper Poitou were Poitiers the capital, Mirebeau, Châtellerault, Richelieu, Loudun, Thouars, Mauléon, Parthenay, Niort, &c., and in Lower Poitou Fontenay-le-Comté, Mailléazes, Luçon and Roche-sur-Yon. Île d’Yeu or Île-Dieu and Noirmoutier belonged to the province. Ecclesiastically, Poitou was a dioce which was broken up in 1317 to form two new dioceses of Luçon and Mailléazes; the seat of the latter was transferred in the 17th century to La Rochelle. For the administration of justice, Poitou was attached to the parlement of Paris. After 776 it formed part of that of Poitou. The name of this region (Poitou, Picotia) takes its name from the Pictonis or Picatii, a Gallic nation mentioned by Caesar, Strabo and Ptolemy, and described by Strabo as separated from the Namnetes on the north by the Loire. It formed part of the territory known as Aquitaine (q.v.).

For the history see the Mémoires of the Société des Antiquaires de l’Ouest (1835 sqq.) and the documents published by the Archives historiques du Poitou (1872 sqq.); also the Dictionnaire topographique de la France, by L. Réjéti (1881).

POKEBERRY, POKEWEED (from the American-Indian powan, applied to any plant yielding a red or yellow dye). In botany, the popular name of Phytolacca decandra, a strong-smelling perennial herb, a native of North America, with ovate-lanceolate sharp-pointed leaves, racemes of small greenish-white flowers and flattish berries nearly \frac{1}{2} in. in diameter, which contain a crimson juice. The young asparagus-like shoots are sometimes used as a pot-herb, but the roots are poisonous. The plant is often cultivated in Europe, and has become naturalized in the Mediterranean region.

POKER, a game at cards. By most writers its origin has been ascribed to Il Frasso, an Italian game of the 15th century, from which the game of Primero, called in Spain Primera, and La Primera in France, in which country it was elaborated into L’Ambigu or Le Masclé. In England the game was played under the name of Post and Pair, of which the modern Brag is only a variation. But Mr R. F. Foster proves that, though poker is probably a descendant of Primero, and perhaps of a much more ancient Persian game called As ras, it is not a development of the English Brag, but was introduced from France into the colony of Louisiana, the name being merely an English mispronunciation of Pogue, a game described as early as 1718 in the Académie universelle des jeux, and still played in Germany under the name Pochen. The earliest mention of the game in America is in G. B. Zieber’s Exposition of the Arts and Miseœts of Gambling (1844), and it is probable that poker was generally played on the Mississippi steamboats as early as 1830, twenty cards being used, “full-deck poker” with 52 cards being invented later. “Draw-poker” was introduced about 1860.

Poker is played for money stakes, markers or “chips” of different value being used. These are either divided equally among the players, or, more usually, one player acts as banker and sells chips to the other players, redeeming them at the end of the game. There are several varieties of the game, but Draw Poker, played by from 2 to 6 or even 7 persons with a pack of 52 cards, is the most popular. The player who wins the cut for deal shuffles the pack, which is then cut by the player at his right. He then deals five cards, one by one, to each player. If a card is faced during the deal the player must accept it; if two are exposed a new deal must ensue. Before the deal is complete the player at the dealer’s left, who is said to hold the age, and is called “the age,” places (or puts up) on the table in front of him half the stake for which he wishes to play. This is called blind. The player at the age’s left then looks at his hand and announces whether he will play. If his hand seems too weak he throws his cards away face-down and “drops out” of the game. If he elects to play he puts up his ante, which is twice the amount of the blind. The other players, including the dealer, then either come in, i.e. elect to play, each putting up an equal stake, or, removing their hands worthless, drop out. The player, who has the last say, may then himself drop out, forfeiting his half-stake already put up, or he may come in and make good his ante, i.e. put up his unpaid half of the blind. Each player in his turn has the privilege of increasing the stake to any amount not exceeding the limit, which is always agreed upon before the game begins. Thus, if the limit is £1, and the age has put up £6. as his blind, any player may, when his turn comes to declare whether he will play, say, “I play and make it £10. (or a sovereign) more to draw cards,” at the same time placing the ante plus £10. (or a sovereign) in the middle of the table. Thereupon all the other players, each in turn, must see the raise, i.e. pay in the additional sum, or drop out of the game, forfeiting what they have already paid into the pool. The “age” being the last to complete, is in the best position to raise, as a player who has already completed is less likely to sacrifice his stake and withdraw from the game. On the other hand each player

1. “Table stakes” means playing strictly for cash; “unlimited” explains itself, although even when this is the rule a certain high limit is pretty generally observed.
POKER

has the right, in his turn, after paying the extra stake called for, of raising it further on his own account, and this goes on until the players who have not dropped out have paid an equal sum into the pool and no one cares to raise further. Each player then throws away as many of his five cards as he chooses and receives from the dealer new ones in their place. In this supplementary deal no player may accept a faced card, but receives one in its place after all the other players have been served.

The number of new cards taken by each one should be carefully noted by the other players, as it gives a valuable clue to the probable value of his hand. The following list shows the highest being, beginning with the lowest.

1. One Pair (accompanied by three cards of different denominations). If two players each hold a pair, the higher wins; if similar pairs (e.g. a pair of kings each) then the next highest card wins.

2. Two Pairs.

3. Triples or Threes of a Kind (e.g. three kings, accompanied by two other cards not forming a pair).

4. Straight, a sequence of five cards, not all of the same suit. Sometimes, but very rarely, these straights are not admitted. An ace may either begin or end a straight. For example: ace, king, queen, jack and 10 is the highest straight; 5, 4, 3, 2, and ace is the lowest. An ace cannot be in the middle. For example, 3, 2, ace, jack, queen and 10 is not a straight.

5. Flush, five cards of the same suit, not in sequence. If two flushes are held, that containing the highest card wins; if the highest card is the same, the next highest wins, &c.

6. Full, or Full House, meaning three cards of the same denomination together with a pair; e.g. three sixes and a pair of fours. If more than one player holds a full, the highest triplet wins.

7. Fours, or four cards of the same denomination; e.g. four queens, which beat four knaves and under.

8. Straight Flush, a sequence of five cards all of the same suit; e.g. knave, 10, 9, 8, 7, of hearts.

9. Royal Flush, the highest possible straight flush; e.g. ace, king, queen, jack, and 10 of spades.

If no player holds at least one pair, then the hand containing the highest card wins.

Each player having received the new cards called for, the betting is opened by the player sitting at the ace's left, should he consider his hand worth it; otherwise he throws away his cards and is out of the game, and the next player (whom we will call C) makes the first bet, which may be of any amount up to the limit, but is usually a small one, with a view to later developments. The next player, D, either drops out, trails, i.e. puts up the amount bet by C (also called seeing and calling), or raises C's bet; in other words puts in the amount bet by C plus as much more (within the limit) as he cares to risk. This raise on D's part means either that he thinks he holds a better hand than C, or that he is trying to frighten C out. The last manoeuvre illustrates the principle of the bluff, the most shrewd feature of the Poker game, with two small pairs in the hand, bets half a crown, and D, with a hand of no value whatever, covers, or sees C's bet and raises it to a sovereign, it is very likely that C will throw down his cards rather than risk a sovereign on his own by no means strong hand. In this case C has been bluffed by D, who, without even having to show his cards, wins the pool, although intrinsically his hand was far inferior to C's. The ability to bluff successfully depends upon self-command, keen observation, judgment and knowledge of character, so as to attempt the bluff when the bluffer is sure that there are no very strong hands out against him. Other wise he will surely be called in his turn, and, having nothing of value, will lose the pool, besides suffering the ignominy of throwing away a large amount of money for nothing.

Two players with strong hands will often raise each other's bets repeatedly, until one of them calls the other, upon which the hands are shown and the stronger wins. The complete hands of the caller and the called must be shown. The common practice of throwing away unshown, for purposes of concealment, a losing hand that has called is illegal. No player who is not called is obliged to show his hand, so that the company is often in doubt whether or not the winner has bluff. When two hands are of exactly equal value the pool is divided.

The game is often varied by a player going blind, i.e. raising the ante before the deal. Another variation is straddling the blind. This is done by the player sitting next the age, who puts up twice the amount of the blind with the words "I straddle." This has the effect of doubling the stake, as every player must then pay twice the amount of the straddle (instead of the blind) in order to play. The straddle may be straddled again in its turn if the aggregate amount does not pass the limit. The straddle does not carry with it the privilege of betting last, but merely raises the amount of the stake.

The regular Draw-Poker game is usually varied by occasional Jack-Pots, which are played once in so many deals, or when all have refused to play, or when the player deals who holds the deck, a marker placed in the pool with every jack-pot. In a jack-pot each player puts up an equal stake and receives a hand.

The pot must then be opened by a player holding a hand of the value of a pair of knaves (jacks) or better. If no player holds so valuable a hand the deal passes and each player adds a small sum to the pot or pool. When the pot is opened the opener does so by putting up any sum he chooses, within the limit, and his companions must pay in the same amount or "drop." They also possess the right to raise the opener. The new cards called for are then dealt and the opener starts the betting, the play proceeding as in the regular game. If Progressive Jack-Pots are played, the minimum value of the opening hand is raised one degree every deal in which the pot is not opened. Thus the opening hand must in the first deal be at least a pair of knaves; but if the pot is not opened the minimum for the second deal is a pair of queens, for the third a pair of kings, &c. Jack-Pots were introduced about 1870.

Straight Poker, or Bluff, is played without drawing extra cards. It was the only variety of the game played, although 52 cards are now used instead of 20, as formerly. The first dealer is provided with a marker called a buck, and having, before dealing, put up the antes of all the players, passes the buck to the next dealer, who must in his turn ante for all when he deals. The rules for betting, raising, &c., are the same as at Draw-Poker. The handicap of course, average smaller.

Stud-Poker is played like Draw-Poker, except that there is no draw and, in dealing, the first card only is dealt face down, the rest being exposed. Each player in turn looks at his turned card and makes his bet or raise. A common variation of Stud-Poker consists in stopping the deal after two cards, one face up and the other face down, have been dealt, and betting on those two cards. A third card is then dealt and betting again takes place, the process being repeated after the fourth and fifth cards have been dealt, the value of the different hands changing with each added card. A player failing to "stand" any raise must refuse from that point and enter his hand.

Whisky-Poker is also played without a draw. An extra hand, called the widow, is dealt to the table face down. The first better then examines his hand and has the option of taking up the widow and placing his own hand on the table face up in its place, or of passing and allowing the following players in turn the choice. After an exposed hand has been laid on the table in place of the widow the next player may either take up one card from the new widow replacing it with one from his own hand, or he may exchange his entire hand for the widow, or he may knock on the table. If he knocks every other player in turn may exchange one card or his whole hand, and the betting them begins, or there may be an agreement that the best hand wins from all the rest, or that the poorest hand pays a chip to the pool.

Technical Terms.

Big Dog.—Ace high and nine low; not usually played. If played it beating a Little Dog.

Blaze.—Five court cards; not usually played. If played it beats any two pairs.

Bluff.—Four cards of a flush or straight, the fifth card not filling.

Bone.—The smallest counter or chip.

Buck.—A marker, to show when a jack-pot is to be played, viz. when it is the holder's deal.

Burnt Card.—Card on the bottom of the pack turned up to prevent being seen.

Chips.—Counters.
Cold Feet.—Any excuse of a winner for leaving the game before the time agreed upon.

Deadwood.—The discard pile.

Deck.—Pack.

Fatten.—Adding chips and a jack-pot after a failure to open.

Freeze Out.—A game in which a player having lost a certain agreed capital must stop playing.

Inside Straight.—Intermediate straight, e.g. 2, 3, 5, 6.

Killer.—Hand with no pair and no card above the nine; seldom played.

Jack.—A fund, to pay for cards or refreshments, made by taking a chip from each jack-pot, or paid by a winner holding a valuable hand.

Jink Dog.—Deuce low and seven high; not usually played.

When played it beats a straight.

Milking.—Shuffling by taking a card from the top and one from the bottom of the pack with the same movement.

Mistigris.—Poker with the joker added; the joker may be called any card the holder chooses.

Monkey Flush.—Three cards of a flush.

Natural Jacks.—Jack-pots played because there has been no ante in the previous deal.

Openers.—A hand on which a jack-pot may be opened.

Pat Hand.—A hand to which no card is drawn.

Pool.—The chips in the middle of the table.

Show-down.—Laying the hands face-up on the table after a call.

Show.—Part of a pool to which a player is entitled who has bet as long as his capital lasted but is not able to stand future raises. If his hand is the best he wins whatever was in the pool at the time when he put into it the last of his capital.

Sky.—Not having put up the jack-pot ante.

Splitting.—Having opened a jack-pot with one pair, and holding for other cards of one suit, to throw away one of the pair on the chance of making a flush.

Sweeten.—Chipping a jack-pot after a failure to open.

Triples.—Three of a kind.

Under the Gun.—The first player to bet.

Whangdoodle.—Compulsory round of jack-pots, usually agreed upon to follow a very large hand.

Widow.—An extra hand dealt to the table, as in Whiskey-Poker.

See Practical Poker, by R. F. Foster (1904), the most authoritative work.

A very important attribute of a successful poker player is sound judgment in discarding, and this is principally based on the following mathematical table of approximate chances.

<table>
<thead>
<tr>
<th>Having in Hand</th>
<th>To make the Hand below.</th>
<th>The Chance is</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 pair</td>
<td>To get two pairs (3-card draw)</td>
<td>1 in 44</td>
</tr>
<tr>
<td>1 pair</td>
<td>To get three of a kind (3-card draw)</td>
<td>1 in 9</td>
</tr>
<tr>
<td>1 pair</td>
<td>To improve either way average value</td>
<td>1 in 3</td>
</tr>
<tr>
<td>1 pair and 1 odd card</td>
<td>To improve either way drawing two cards</td>
<td>1 in 7</td>

</table>

Of course these chances are somewhat improved by the fact that, in actual play, pairs and threes are, on account of careless shuffling, apt to lie together more or less.

POLA (Gr. Πόλη or Πολί; Slovene, Polj), a seaport of Austria, in Istria, 86 m. S. of Trieste by rail. Pop. (1900), 45,052. It is the principal naval harbour and arsenal of the Austro-Hungarian monarchy, and is situated near the southern extremity of the peninsula of Istrija. It lies at the head of the Bay of Pola, and possesses a safe and commodious harbour almost completely landlocked. An extensive system of fortifications, constructed on the hills, which enclose the harbour, defends its entrance, while it also possesses a good roadstead in the large channel of Fasana. This channel separates the mainland from the Brioni Islands, which dominate the entrance to the bay. The harbour has an area of 672 sq. m., and is divided into two basins by a chain of three small islands. The inner basin is subdivided by the large Olive Island into the naval harbour, lying to the south, and the commercial harbour, lying to the north. The Olive Island is connected with the coast by a chain-bridge, and is provided with wharfs and dry and floating docks. The town proper lies opposite the Olive Island, round the base of a hill formerly crowned by the Roman capitol and now by a castle from the 17th century. Besides the castle the chief buildings are the cathedral, dating from the 12th century; the new garrison church, completed in 1808 in the Basilica style, with a fine marble façade; the Franciscan convent dating from the 14th century, and now used as a military magazine; the huge infantary barracks; and the town-hall, dating from the beginning of the 14th century. To the south-west, along the coast, extends the marine arsenal, a vast and well-planned establishment possessing all the requisites for the equipment of a large fleet. It contains an interesting naval museum, and is supplemented by the docks and wharves of the Scoglio Olivi. The artillery laboratory and the powder magazine are on the north bank of the harbour. Behind the arsenal lies the suburb of San Policarpo, almost exclusively occupied by the naval population and containing large naval barracks and hospitals. In the middle of it is a pleasant park, with a handsome monument to the emperor Maximilian of Mexico, who had been a rear-admiral in the Austrian navy. To the north, between San Policarpo and the town proper, rises the Monte Zaro, surmounted by an observatory and a statue of Admiral Tegetthoff. Pola has no manufactures outside of its naval stores, but its shipping trade is now considerable, the exports consisting of fish, timber and quartz sand used in making Venetian glass, and the imports of manufactured and colonial wares. To many people, however, the chief interest of Pola centres in its fine archaeological remains. The most remarkable of these is the amphitheatre built in a.D. 198-211, in honour of the emperors Septimius Severus and Caracalla, which is 70 ft. high, 400 ft. long and 320 ft. wide, and could accommodate 20,000 spectators. It is remarkable as the only Roman amphitheatre of which the outer walls have been preserved intact; the interior, however, is now completely bare—though the arrangements for the naumachia, or naval contests, can still be traced. The oldest Roman relic is the fine triumphal arch of the Christian temple, erected soon after the battle of Actium; and of not much later date is the elegant and well-preserved temple of Augustus and Roma erected in the year 19 B.C. Among the other antiquities are three of the old town gates and a fragment of a temple of Diana.

The foundation of Pola is usually carried back to the mythic period, and ascribed to the Colchian pursuers of Jason and the Argonauts. In all probability it was a Thracian colony, but its verifiable history begins with its capture by the Romans in 178 B.C. It was during the time of Augustus, after the emission of the cause of Pompey, but was rebuilt on the intercession of his daughter Julia, and received (according to Pliny) the name of Pietas Julia. It became a Roman colony either
under the triumviri or under Octavian, and was mainly important as a harbour. It seems to have attained its greatest prosperity about the time of the emperor Septimius Severus (193–212 A.D.), when it was an important war harbour and contained 35,000 to 60,000 inhabitants. At a later period Pola became the capital of the margraves of Istria, and was captured by the Venetians in 1148. It was several times captured and plundered by the Genoese, and recaptured by the Venetians. In 1379 the Genoese, after defeating the Venetians in a great naval battle off the coast, took and destroyed Pola, which disappears from history for the next four hundred and fifty years. It remained under Venetian supremacy down to 1797, and has been permanently united with Austria since 1815. In 1848 a new era began for Pola in its being selected as the principal naval harbour of Austria.

See Th. Mommsen in Corp. Inschr. Latin., v. 3 sqq. (Berlin, 1883); T. G. Jackson, Dalmatia, the Quaere and Istria., vol. iii. (Oxford, 1887).

POLABS (Pe—on, Labae—Elbe), the Slavs (q.v.) who dwelt upon the Elbe and eastwards to the Oder. Their chief tribes were the Vagri in Holstein, the Bodriči or Obotritae in Mecklenburg, the Ljutiči or Wiltzi in western Pomerania, the Sprevane on the Spree and the Glomač or Daleminti in Saxony. Except the Lithuanians they were the last Europeans to be christianized; their chief sanctuary was at Arcona on the Isle of Rügen. They were converted and conquered by the 12th century and systematically germanized. By the 15th century Slavonic survived only in a tiny patch in the east of Hanover about Lichow, where a few words were still understood at the beginning of the 19th century. The population of the district still goes by the name of Wends (q.v.). The chief remains of the language are a paternoster, a few phrases and a short vocabulary written down by Pastor Chr. Henning (c. 1700), and the diary of J. Paruns Schultz (d. 1734). These were edited by A. Hilferding (St Petersburg, 1856), and a grammar was published there by A. Schleicher (1871). M. Porzeznicki and Fr. Lorentz are the chief later authorities. Polabian agrees mostly with Polish and Kashe with its nasalized vowels and highly palatalized consonants. It had, however, long vowels and a free accent. The remains of it are most corrupt, having been written down when the language was still live of German by people who did not know Slavonic.

POLACCA, the Italian name for a three-masted merchant vessel, formerly common in the eastern waters of the Mediterranean. The masts were of one piece and the sails were square or lateen-shaped. The name appears in various forms in other languages, e.g. Fr. polaque or polacre, Sp. polaca, Du. polak or Ger. Polack, and certainly means Polish, although there is no explanation to be found for any connexion between Poland and such a Mediterranean vessel.

POLAND (Polish Polska, Ger. Polen), (see Poland, Russian, below), a country of Europe which till the end of the 18th century was a kingdom extending (with Lithuania) over the basins of the Warta, Vistula, Dwina, Dnieper and upper Dniester, and had under its dominion, besides the Poles proper and the Baltic Slavs, the Lithuanians, the White Russians and the Little Russians or Ruthenians.

We possess no certain historical data relating to Poland till the end of the 10th century. It would seem, from a somewhat obscure passage in the chronicle compiled from older sources by Nestor, a monk of Kiev (d. c. 1115), that the progenitors of the Poles, originally established on the Danube, were driven from thence by the Romans to the still wilder wilderness of central Europe, settling finally among the wild tribes inhabiting the bank of the upper waters of the Oder and the Vistula. Here the Lachii, as they called themselves (a name derived from the mythical patriarch, Lech), seemed to have lived for centuries, in loosely connected communities, the simple lives of huntsmen, herdsmen and tillers of the soil, till the pressure of rapacious neighbours compelled them to combine for mutual defence. Of this state, the so-called kingdom of the Piasts (from Piast its supposed founder), we know next to nothing. Its origin, its territory, its institutions are so many insoluble riddles. The earliest Polish chronicles, from Gallus in the early 12th century to Janko of Casimir, in the 14th, are of little help to us. The only facts of importance to be gleaned from them are that Prince Ziemovit, the great-grandfather of Mieszko (Mieczyslaw) I. (992–1025), wrested from the vast but tottering Moravian Empire the province of Chrobacyja (extending from the Carpathians to the Bug), and that Christianity was first preached on the Vistula by Greek Orthodox missionary monks. Mieszko himself was converted by Jordan, the chaplain of his Bohemian consort, Dobrava or Bona, and when Jordan became the first bishop of Posen, the people seemed to have followed the example of their prince. But the whole movement was apparently the outcome not of religious conviction, but of political necessity. The Slavonic peoples, whose territories then extended to the Elbe, and embraced the whole southern shore of the Baltic, were beginning to recollect before the vigorous impetus of the Germans in the West, who regarded their pagan neighbours in much the same way as the Spanish Conquistadores regarded the Aztecs and the Incas. To accept Christianity, at least formally, was therefore a prudential safeguard on the part of the Slavonians. This was thoroughly understood by Mieszko's son Boleslaus I. (992–1025), who went a considerable step farther than his father. Mieszko had content to be received on almost any terms into the Christian community, Boleslaus aimed at securing the independence of the Polish Church as an additional guarantee of the independence of the Polish nation.

It was Boleslaus who made the church at Gnesen the national shrine of Poland. His name, by Gnesen, is shown to be the root of Gnesen, in Great Poland a national shrine by translating the relics of the martyred missionary, St Adalbert of Prague. Subsequently he elevated Gnesen into the metropolitan see of Poland, with jurisdiction over the bishoprics of Cracow, Breslau and Kolberg, all three of these new sees, it is important to notice, being in territory conquered by Boleslaus; for hitherto both Cracow and Breslau had been Bohemian cities, while Kolberg was founded to curb the lately subdued Pomeranians. Boleslaus was also the first Polish prince to bear the royal title, which seems to have been conferred upon him by Otto III. in 1000, though as Boleslaus crowned himself king a second time in 1025, it is evident that he regarded the validity of his first coronation as somewhat doubtful. He was primarily a warrior, whose reign, an almost uninterrupted warfare, resulted in the formation of a vast kingdom extending from the Baltic to the Carpathians, and from the Elbe to the Bug. But this imposing superstructure rested on the flimsiest of foundations. In less than twenty years after the death of its founder, it collapsed before a combined attack of all Poland's enemies, and simultaneously a terrible pagan reaction swept away the poor remnants of Christianity and civilization. For a time Poland proper became a smoking wilderness, and wild beasts made their lairs in the ruined fortified churches. Under Boleslaus II. (1058–1079) and Boleslaus III. (1102–1139) some of the lost provinces, notably Silesia and Pomerania, were recovered and Poland was at least able to maintain her independence against the Germans. Boleslaus III., moreover, with the aid of St Otto, bishop of Bamberg, succeeded in converting the heathen Pomeranians (1124–1125), and making head against paganism generally.

The last act of Boleslaus III. was to divide his territories among his sons, whereby Poland was partitioned into no fewer than four, and ultimately into as many as eight, Partitional principalities, many of which (Silesia and Greater Poland, for instance) or Carpathian forested up into still smaller fractions all of them more or less bitterly hostile to each other. This partitional period, as Polish historians generally call it, lasted from 1138 to 1305, during which Poland lost all political significance, and became an easy prey to her neighbours. The duke of Little Poland, 1 Archdeacon of Gnesen 1367; vice-chancellor of Poland; d. c. 1387.

1
who generally styled himself duke of Poland, or \textit{dux totius Poloniae}, claimed a sort of supremacy among these little states, a claim materially strengthened by the wealth and growing importance of his capital, Cracow, especially after Little Poland had annexed the central principality of Sieradz (Sieradz). But Masovia to the north, and Great Poland to the north-west, refused to recognize the supremacy of Little Poland, while Silesia soon became completely Germanized. It was at the beginning of this period too, between 1216 and 1224, that Pomerania, under an energetic native dynasty, freed herself from the Polish suzerainty. Nearly a generation later (1241) the Tatar hordes, under Batu, appeared for the first time on the confines of Poland. The Polish princes opposed a valiant but ineffectual resistance; the towns of Sandomir and Cracow were reduced to ashes, and all who were able fled to the mountains of Hungary or the forests of Moravia. Pursuing his way to Silesia, Batu overthrew the confederated Silesian princes at Liegnitz (April 9), and, after burning all the Silesian towns, invaded Hungary, where he routed King Béla IV. on the banks of the Sajo. But this marked the limit of his triumph. Exhausted and diminished by the stout and successful opposition of the Moravians at Olmütz, the Tatars vanished as suddenly as they had appeared, leaving a smoking wilderness behind them.

Batu’s invasion had an important influence upon the social and political development of Poland. The only way of filling up the gaps in the population of the ravaged land was to invite foreign immigrants of a superior class, chapmen and handicraftsmen, not only given to peaceful pursuits and accustomed to law and order, but capable of building and defending strong cities. Such immigrants could naturally be obtained only from the civilized west, and on their own terms. Thus it came about that the middle class element was introduced into Polish society for the first time. Immediately dependent upon the prince, from whom they obtained their privileges, the most important of which were self-government and freedom from taxation, these traders soon became an important factor in the state, counterpoising, to some extent, the influence of the gentry, enriching the land by developing its resources, and promoting civilization by raising the standard of comfort.

Most of these German citizens in process of time were absorbed by the Poles, and became devoted, heart and soul, to the \textit{Knights of the Sword}. This was to their adopted country; but these were not the only Germans with whom the young Polish state had now to deal. In the first year of the 13th century, the \textit{Knights of the Sword}, one of the numerous orders of crusading military monks, had been founded in Livonia to “convert” the pagan Letts, and, in 1208, the still more powerful Teutonic order was invited by Duke Conrad of Masovia to settle in the district of Kulm (roughly corresponding to modern East Prussia) to protect his territories against the incursions of the savage Prussians, a race closely akin to the Lithuanians. Conrad had been loudly blamed by Polish historians for introducing this threat and as the result of the so-called BAUDAS, many elements were brought into Poland. But the unfortunate prince had to choose between dependence and extermination, for his unaided resources were powerless against the persistent attacks of the unconquerable Prussians. The Teutonic Order, which had just been expelled from Hungary by Andrew II., “joyfully” accepted this new domicile, and its position in the north was definitely established by the compact of Kruszwitz in 1230, whereby it obtained absolute possession of the maritime district between Pomerania and Courland, and southwards as far as Thorn. So far were the Poles from anticipating any danger from the Teutonic Order, that, from 1243 to 1255, they actually assisted it to overthrow the independent Pomerian principality, the most formidable opponents of the Knights in the earlier years of their existence. A second Tatar raid in 1259, less dangerous, perhaps, but certainly more ruinous, than the first invasion—for the principalities of Little Poland and Sandomir were systematically ravaged for three months—still further depressed the land, and, at this very time, another enemy appeared in the east—the Lithuanians.

This interesting people, whose origin is to this day the most baffling of ethnographical puzzles, originally dwelt amidst the forests and marshes of the Upper Niemen. Thanks to the impenetrability of their fastnesses, they preserved their original savagery longer than any of their neighbours, and this savagery was coupled with a valour so tenacious and enterprising as to make them formidable to all who dwelt near them. The Russians fled at the sight of them, “like hares before hunters.” The Livs and Letts were as much the prey of the Lithuanians “as sheep are the prey of wolves.” The German chroniclers describe them as the most terrible of all the barbarians. The Lithuanians first emerge into the light of history at the time of the settlement of the Teutonic Order in the North. Rumours of the war of extermination conducted against their kinsmen, the wild Prussians, by the Knights, first woke the Lithuanians to a sense of their own danger, and induced them to abandon their loose communal system in favour of a monarchial form of government, which concentrated the whole power of the state in a single hand. Fortunately, too, at this crisis of their history, the Lithuanians were blessed with an altogether exceptional series of great rulers, who showed themselves fully capable of taking care of themselves. There was, for instance, Mendovg (1240-1263), who submitted to baptism for purely political reasons, checked the Teutonic Knights by adroitly seeking the protection of the Holy See, and annexed the principality of Plock to his ever-widening grand duchy, which already included Black Russia, and formed a huge wedge extending southwards from Courland, thus separating Poland from Russia. A still greater prince was Gedymin (1315-1342), who did his utmost to civilize Lithuania by building towns, introducing foreigners, and tolerating all religions, though he himself remained a pagan for political reasons. Gedymin still further extended the limits of Lithuania by annexing Kiev, Chernigov and other Russian principalities.

At the very time when Lithuania was thus becoming a compact, united, powerful state, Poland seemed literally to be dropping to pieces. Not even the exhortations of the popes could make her score of princes unite for mutual defence against the barbarians who were menacing them. For they were perhaps the most probable that Poland would be completely Germanized, like Silesia, or become a part of the new Bohemian Empire which Wenceslaus II. (crowned king of Poland in 100) had inherited from his father, Ottakar II. From this fate she was saved by the valour of Wladislaus Lokietek, duke of Great Poland (1306-1333), who united Great and Little Poland, revived the royal dignity in 1320, and saved the kingdom from annihilation by his great victory over the Teutonic Knights at Plowce in 1332. The whole reign of Wladislaus I. was indeed an unceasing struggle against all the forces of anarchy and disintegration; but the fruits of his labours were richly reaped by his son Casimir III. The great sovereign of the 14th century was a type of the modern sense of the word, who, by a most skilful system of matrimonial alliances, reintroduced isolated Poland into the European system, and gave the exhausted country an insensibly beneficial breathing space of thirty-seven years. A born ruler, Casimir introduced a whole series of administrative and economical reforms. He was the especial protector of the cities and the peasants, and, though averse from violent measures, punished aristocratic tyranny with an iron hand. Casimir’s few wars were waged entirely for profit, not glory. It is to him that Poland owed the important acquisition of the greater part of Red Russia, on Galicia, which enabled her to secure her fair share in the northern and eastern trade. In default of male issue, Casimir left the Polish throne to his nephew, Louis of Hungary, who ruled the country (1370-1382) through his mother, Queen Elizabeth, Wladislaus Lokietek’s daughter. Louis well deserved the epithet of “great ” bestowed upon him by his contemporaries;
but Poland formed but a small portion of his vast domains, and Poland's interests were subordinated to the larger demands of an imperial policy which embraced half Europe within its orbit.

On the death of Louis there ensued an interregnum of two years marked by fierce civil wars, instigated by duke Ziemovit of Masovia, the northernmost province of Poland, which continued to exist as an independent principality alongside of the kingdom of Poland. Ziemovit aimed to the Polish crown, proposing to marry the infant princess Jadwiga of Hungary, who, as the daughter of Louis the Great and the grand-daughter of Wladislaus Lokie.t, had an equal right, by inheritance, to the thrones of Hungary and Poland. By an agreement with the queen mother of Hungary at Kassa in 1383, the Poles finally accepted Jadwiga as their queen, and, on the 18th of February 1386, greatly against her will, the young princess, already betrothed to William of Austria, was wedded to Jagiello, grand duke of Lithuania, who had been crowned king of Poland at Cracow, three days previously, under the name of II.

The union of Poland and Lithuania as separate states under one king had been brought about by their common fear of the Teutonic Order. Five years after the death of Gedymyn, Olgierd, the most capable of his seven sons, had been placed upon the throne of Lithuania by his devoted brother Kiejstut, and for the next two-and-thirty years (1345-1377) the two princes still further extended the sway of Lithuania, principally at the expense of Muscovy and the Tatars. Kiejstut ruled the western portion of the land where the Teutonic Knights were a constant menace, while Olgierd drove the Tartar hordes out of the southern steppes, and compelled them to seek a refuge in the Crimea. During Olgierd's reign the southern boundaries of Lithuania touched the Black Sea, including the whole tract of land between the mouth of the Bug and the mouth of the Dnieper. Olgierd was succeeded by his son Jagiello as grand duke in 1377, while Kiejstut was left in possession of Samogitia, Troki and Grodno; but the Teutonic Order, alarmed at the growth of Lithuania, succeeded in estranging uncle and nephew, and Kiejstut was treacherously assassinated by Jagiello's orders, at Krewo, on the 15th of August 1382. Three weeks later Jagiello was compelled to cede Samogitia, as far as the Dubissa, to the Knights, and, in the following year they set up against him Kiejstut's son Witewt. The eyes of Jagiello were now opened to the fact that the machiavellian policy of the Knights was aimed at subjugating Lithuania by dividing it. He at once made peace with his cousin; restored him his patrimony; and, to secure Lithuania against the future vengeance of the Knights, Jagiello made overtures to Poland for the hand of Jadwiga, and received the Polish crown along with it, as already mentioned.

Before proceeding to describe the Jagiellonian period of Polish history, it is necessary to cast a rapid glance at the social and political condition of the country in the preceding Piast period.

The paucity and taciturnity of our sources make it impossible to give anything like an adequate picture of Old Poland during the first four centuries of its existence. Generally speaking, here and there of the political development of the country is the utmost that the most diligent scrutiny can glean from the scanty record of the early chronicles. External pressure, here as elsewhere, created a patriotic military caste, and the subsequent partial period, when every little prince had his own separate court, still further established the growing influence of the szlachta, or gentry, who were not backward in claiming and obtaining special privileges in return for their services. The first authentic pacta conventa made between the Polish nobility and the Crown dates from the compact of Kassa (September 17, 1374), when Louis of Hungary agreed to exempt the szlachta from all taxation, except two Polish groschen per hide of land, and to compensate them for the expenses of all military service rendered beyond the confines of the realm. The clergy received their chief privileges much earlier. It was at the synod of Leczycy, nearly a century before the compact of Kassa, that the property of the Church was first safeguarded against the encroachments of the state. The beneficial influence of the Church of Poland in these early times was incalculable. To say nothing of the labours of the Cistercians as colonists, pioneers and church-builders, or of the missions of the Dominicans and Franciscans (the former of whom were introduced into Poland by Ivo, bishop of Cracow, the personal friend of Dominic), the Church was the one stable and unifying element in an age of centrifugal particularism. The frequent synods represented the whole of Poland, and kept alive, as nothing else could, the idea of national solidarity. The Holy See had also a considerable share in promoting the political development of the land. In the 15th century alone no fewer than forty-nine papal legates visited Poland, and thirty provincial synods were held by them to regulate church affairs and promote good government. Moreover the clergy, to their eternal honour, consistently protected the lower from the tyranny of the upper classes.

The growth of the towns was slower. During the heroic Bohemian period there had been a premature outcrop of civil life. As early as the 14th century Krakow, the old Polish capital, and Gnesen, the metropolitan see, were of considerable importance, and played a leading part in public life. But in the ensuing anarchy period both cities were utterly ruined, and the centre of political gravity was transferred from Great Poland to Little Poland, where Cracow, singularly favoured by her position, soon became the capital of the monarchy, and one of the wealthiest cities in Europe. At the end of the 14th century we find all the great trade guilds established there, and the cloth manufactured at Cracow was eagerly sought after, from Prague to Great Novgorod. So wealthy did Cracow become at last that Casimir the Great felt it necessary to restrain the luxury of her citizens by summary ordinances. Towards the end of the 14th century the Polish towns even attained some degree of political influence, and their delegates sat with the nobles and clergy in the king's councils, a right formally conceded to them at Radom in March 1384. Even the peasants, who had suffered severely from the wholesale establishment of prisoners of war as serfs on the estates of the nobles, still preserved the rights of personal liberty and free transit from place to place, whence their name of lanigi. The only portion of the community which had no privileges were the Jews, first introduced into Poland by Boleslaus the Pious, but by the 13th century they were being driven from the country, and began their career of bondage from the shores of the Adriatic. Casimir the Great extended their liberty of domicile over the whole kingdom (1334). From the first they were better treated in Poland than elsewhere, though frequently exposed to outbreaks of popular fanaticism. The transformation of the pagan Lithuanian chieftain Jagiello into the catholic king of Poland, Wladislaus II., was an event of capital importance in the history of eastern Europe. Its immediate and inevitable consequence was the formal reception of the Lithuanian nations into the fold of the Church. What the Teutonic Order had been unable to bring about by fire and sword, was peacefully accomplished by Jagiello within a single generation, the Lithuanians, for the most part, willingly yielding to the arguments of a prince of their own blood, who promptly rewarded his converts with peculiar and exclusive privileges. The conversion of Lithuania menaced the very existence of the Teutonic Knights. Originally planted on the Baltic shore for the express purpose of christianizing their savage neighbours, these crusading monks had freely exploited the wealth and the valour of the West, ostensibly in the cause of religion, really for the purpose of founding a dominion of their own which, as time went on, lost more and more of its religious character, and was now more and more of a Germanic forepost, extending from Pomerania to the Niemen, which deliberately excluded the Slavs from the sea and thrived

1 Archbishop of Gnesen 1219-1220. Died at Modena 1229.
at their expense. The mere instinct of self-preservation had, at last, drawn the Poles and Lithuanians together against these ruthless and masterful intruders, and the coronation of Jagiello at Cracow on the 15th of February 1453, was both a warning and a challenge to the Knights. But if the Order had now become a superfluity anachronism, it had still to be disposed of, and there was no lack of suitors. For it had failed to revictual in partibus; it had succeeded in establishing on the Baltic one of the strongest military organizations in Europe. In the art of war the Knights were immeasurably superior to all their neighbours. The pick of the feudal chivalry composed their ranks; with all Europe to draw upon, their resources seemed inexhaustible, and centuries of political experience made them as formidable in diplomacy as they were valiant in warfare. And indeed, for the next twenty years, the Teutonic Order more than held its own. Skillfully taking advantage of the jealousies of Poland and Lithuania, as they were accentuated by the personal antagonism of Jagiello and Witowt (q.v.), with the latter of whom the Knights more than once contracted profitable alliances, they even contrived (Treaty of Sallia, 1378) to extend their territory by getting possession of the province of Samogitia, the original seat of the Lithuanians, where paganism still persisted, and where their inhuman cruelties finally excited the horror and indignation of Christian Europe. By this time, however, the prudent Jagiello had become convinced that Lithuania was too strong to be ruled by or from Poland, and yet not strong enough to stand alone, and by the compact of Vilna (January 18, 1401, confirmed by the compact of Radowo, March 16) he surrendered the whole grand duchy to Lithuania on three conditions that the two states should have a common policy, and that neither of them should elect a new prince without the consent of the other. The wisdom of this arrangement was made manifest in 1410, when Jagiello and Witowt combined their forces for the purpose of delivering Samogitia from the intolerable tyranny of the Knights. The issue was fought out on the field of Tannenberg, or Grünwald (July 15, 1410), when the Knights sustained a crushing defeat, which shook their political organization to its very foundations. A few weeks after the victory the towns of Thorn, Elbing, Braunsberg and Danzig submitted to the Polish king, and all the Prussian bishops voluntarily offered to render him homage. Jagiello, the young grand-duke, who had contrived his elevation to the throne, now took the opportunity, as governor, to put the Knights time to recover from the blow; the Polish levies proved unruly and incompetent; Witowt was suddenly recalled to Lithuania by a Tatar invasion, and thus it came about, that when peace was concluded at Thorn, on the 1st of February 1411, Samogitia (which was to revert to the Order on the death of Jagiello and Witowt), Dobrzyn, and a war indemnity of 100,000 marks payable in four instalments, were the best terms Poland could obtain from the Knights, whose territory practically remained intact. Jagiello's signal for the attack at the battle of Grünwald, "Cracow and Vilna" (the respective capitals of Poland and Lithuania) had illogically demonstrated the solidarity of the two states. This solidarity was still further strengthened by the Union of Horodlo (October 2, 1413), which enacted that henceforth Lithuania was to have the same order of dignitaries as Poland, as well as a council of state, or senate, similar to the Polish senate. The power of the grand-duke was also greatly increased. He was now declared to be the equal of the Polish king, and his successor could be elected only by the senators of Poland and Lithuania in conjunction. The Union of Horodlo also established absolute parity between the nobility of Poland and Lithuania, but the privileges of the latter were made conditional upon their profession of the Roman Catholic faith, experience having shown in the dispute of religion in Lithuania the total difference of politics, and a tendency Moscow-wards, the majority of the Lithuanian boyars being of the Greek Orthodox Confession.

All the chief offices of state were consequently duplicated, e.g. the hetman wielki koronnny, i.e. "grand hetman of the crown," as the Polish commander-in-chief was called, had his counterpart in Lithuania, who bore the title of wielki hetman iwiencki, i.e. "grand hetman of Lithuania," and so on.

During the remainder of the reign of Wladislaus II. the Teutonic Order gave Poland much trouble, but no serious anxiety. The trouble was due mainly to the repeated efforts of the Knights to evade the fulfilment of the obligations of the Treaty of Thorn. In these endeavours they were materially assisted by the emperor Sigismund, who was also king of Hungary. Sigismund, who succeeded his father King Wladislaus II., was extremely fond of promoting a partition of Poland between Hungary, the empire and the Silesian princes, a scheme which floundered under Sigismund's imprudence and the reluctance of the Magyars to injure the Poles. More than once Wladislaus II. was even obliged to renew the war against the Knights, and, in 1422, he compelled them to renounce all claims upon Samogitia; but the long struggle, still undecided at his death, was fought mainly with diplomatic weapons at Rome, where the popes, generally speaking, listened rather to the victorious monarch who had added an ecclesiastical province to the Church than to the discomfited and turbulent Knights.

Had Wladislaus II. been as great a warrior as Witowt he might, perhaps, have subdued the Knights altogether. But by nature he was pre-eminently a diplomatist, and it must in fairness be admitted that his diplomacy in every direction was distinctly beneficial to Poland. He successfully thwarted all the schemes of the emperor Sigismund, by artfully supporting the revolutionary party in Bohemia (q.v.). In return Hussite mercenaries fought on the Polish side at Tannenberg, and Czech patriots repeatedly offered the crown of Bohemia to Wladislaus. The Polish king was always ready enough to support the Czechs against Sigismund; but the necessity of justifying his own orthodoxy (which the Knights were for ever impugning) at Rome and in the face of Europe prevented him from accepting the crown of St Wenceslaus from the hands of heretics.

Wladislaus II. died at Lemberg in 1434, at the age of eighty-three. During his long reign of forty-nine years Poland had gradually risen to the rank of a great power, a result due in no small measure to the insight and sagacity of the first Jagiello, who sacrificed every other consideration to the vital necessity of welding the central Slavs into a compact and homogeneous state. The next ten years severely tested the stability of his great work, but it stood the test triumphantly. Neither a great pretender, in 1422, nor an aggressive king, nor even the revival of separatist tendencies in Lithuania, nor the outbreaks of aristocratic lawlessness in Poland, could do more than shake the superstructure of the imposing edifice. After the death at Varna, in 1444, of Jagiello's eldest son and successor, Wladislaus III. (whose history belongs rather to Hungary than to Poland), another great statesman, in no wise inferior to Wladislaus II., completed and consolidated his work. This was Wladislaus' second son, already grandduke of Lithuania, who ascended the Polish throne as Casimir IV, in 1447, thus reuniting Poland and Lithuania under one monarch.

Enormous were the difficulties of Casimir IV. He instinctively recognized not only the vital necessity of the maintenance of the union between the two states, but also the fact that the chief source of danger to the union lay in Lithuania, in those days a maelstrom of conflicting political currents. To begin with, Lithuania was a far less composite state than Poland. Two-thirds of the grandduchy consisted of old Russian lands inhabited by men who spoke the Ruthenian language and professed the Orthodox Greek religion, while in the north were the Lithuanians proper, semi-savage and semi-catholic, justly proud of their heroic forefathers of the house of Gedimin, and very sensitive of the pretensions of Poland to the provinces of Volhynia and Podolia, the fruits of Lithuanian valor. A Lithuanian himself, Casimir strenuously resisted the attempts of Poland to wrest these provinces from the grandduchy. Moreover, during the earlier years of his reign, he was obliged to reside for the most part in Lithuania, where his tranquillizing influence was needed. His supposed preference for Lithuania was the real cause of his unpopularity in Poland, where, to the very end of his reign, he was regarded
with suspicion, and where every effort was made to thwart his far-seeing and patriotic political combinations, which were beyond the comprehension of his self-seeking and narrow-minded contemporaries. This was notably the case as regards his dealings with the old enemy of his race, the Teutonic Order, whose destruction was the chief aim of his ambition.

The Teutonic Order had long since failed as a religious institution; it was now to show its inadequacy as a political organization. In the domain of the Knights the gentry, parochial clergy and townsmen, who, beneath its protection, had attained to a high degree of wealth and civilization, for long remained without the slightest political influence, though they bore nearly the whole burden of taxation. In 1414, however, intimidated by the growing discontent, which frequently took the form of armed rebellion, the Knights consented to the establishment of a diet, which was re-formed on a more aristocratic basis in 1430. But the old abuses continuing to multiply, the Prussian towns and gentry at last took their affairs into their own hands, and formed a so-called Prussian League, which demanded an equal share in the government of the country. This league was comprised of the cities in which the Knights had embarked upon the empire almost simultaneously in 1453, whereupon it placed itself beneath the protection of its nearest powerful neighbour, the king of Poland, who (March 6, 1454) issued a manifesto incorporating all the Prussian provinces with Poland, but, at the same time, granting them local autonomy and free trade.

But provinces are not conquered by manifestoes, and Casimir’s acceptance of the homage of the Prussian League at once involved him in a war with the desperate Teutonic Knights, which lasted twelve years, but might easily have been concluded in a twelvemonth had he only been loyally supported by his own subjects, for whom he had embarked upon the great enterprise. But instead of support, Casimir encountered obstinate obstruction at every point. No patriotic Pole, we imagine, can read the history of this miserable war without feeling heartily ashamed of his countrymen. The acquisition of the Prussian lands was vital to the existence of Poland. It meant the excision of an alien element which fed like a cancer on the body politic; it meant the recovery, at comparatively little cost, of the command of the principal rivers of Poland, the Vistula and the Niemen; it meant the obtaining of a seaport with the corollaries of sea-power and world-wide commerce. Yet, except in the border province of Great Poland, which was interested commercially, the whole enterprise was regarded with such indifference that the king, in the very crisis of the struggle, could only with the utmost difficulty obtain contributions for war expenses from the half-dozen local diets of Poland, which extorted from the helplessness of their distracted and impecunious sovereign fresh privileges for every subsidy they grudgingly granted. Moreover Casimir’s difficulties were materially increased by the necessity of paying for Czech mercenaries, the pospolite ruszenie, or Polish militia, proving utterly useless at the very beginning of the war. Indeed, from first to last, the Polish gentry as a body took good care to pay and fight as little as possible, and Casimir depended for the most part upon the gentry and the Prussian towns, and the valour of the Hussite infantry, 170,000 of whom, fighting on both sides, are said to have perished. Not till the victory of Puck (September 17, 1462), one of the very few pitched battles in a war of raids, skirmishes and sieges, did fortune incline decisively to the side of the Poles, who maintained and improved their advantage till absolute exhaustion compelled the Knights to accept the mediation of a papal legate, and the second peace of Thorn (October 14, 1466) concluded a struggle which had reduced the Prussian provinces to a wilderness. 1

By the second peace of Thorn, Poland recovered the provinces of Pomerelia, Kulm and Michalow, with the bishopric of Ermland, numerous cities and fortresses, including Marien- burg, Elbing, Danzig and Thorn. The territory of the Knights was now reduced to Prussia proper, embracing, roughly speaking, the district between the Baltic, the lower Vistula and the lower Niemen, with Königsberg as its capital. For this territory the grand-masters, within nine months of their election, were in future to render homage to the Polish king; but, on the other hand, the king undertook not to make war or engage in any important enterprise without the consent of the Prussian province, and vice versa. Thus Prussia was now confederated with Poland, but she occupied a subordinate position as compared with Lithuania, inasmuch as the grand-master, though filling the first place in the royal council, was still a subject of the Polish crown. Thus the high hopes entertained by Casimir at the beginning of the war had not been realized. The final settlement with the Poles was of the nature of a compromise. Still the Knights had been driven beyond the Vistula, and Poland had secured a seaport; and it was due entirely to the infinite patience and tenacity of the king that even as much as this was won at last.

The whole foreign policy of Casimir IV. was more or less controlled by the Prussian question, and here also his superior diplomacy triumphantly asserted itself. At the beginning of the war both the empire and the pope were against him, but he neutralized their hostility by appealing himself to George of Podiebrad, whom the Hussites had placed on the throne of Bohemia. On the death of George, Casimir’s eldest son Vladislaus was elected king of Bohemia by the Utraquist party, despite the determined opposition of Matthias Corvinus, king of Hungary, whose ability and audacity henceforth made him Casimir’s most dangerous rival. Sure of the support of the pope, Matthias (q.v.) deliberately set about traversing all the plans of Casimir. He encouraged the Teutonic Order to rebel against Poland; he entertained at his court anti-Polish embassies from Moscow; he encouraged the Tartars to ravage Lithuania; he thwarted Casimir’s policy in Moldavia. The death of the brilliant adventurer at Vienna in 1490 came therefore as a distinct relief to Poland, and all danger from the side of Hungary was removed in 1490 when Casimir’s son Vladislaus, already king of Bohemia, was elected king of Hungary also.

It was in the reign of Casimir IV. that Poland first came into direct collision with the Turks. The Republic was never, indeed, the “Buckler of Christendom.” That glorious epithet belonged of right to Hungary, which had already borne the brunt of the struggle with the Ottoman power for more than a century. It is true that Vladislaus II. of Poland had fallen on the field of Varna, but it was as a Magyar king at the head of a Magyar army that the young monarch met his fate. Poland, indeed, was far less able to cope with the Turks than compact, wealthy Hungary, which throughout the 13th century was one of the most efficient military monarchies in Europe. The Jagiellons, as a rule, prudently avoided committing themselves to any political system which might irritate the still distant but much-dreaded Turk, but when their dominions extended so far southwards as to embrace Moldavia, the observance of a strict neutrality was impossible. The unity and integrity of Poland and Lithuania had established a sort of suzerainty over Moldavia as early as the end of the 14th century; but at best it was a loose and vague overlordship which the Hospodars repudiated whenever they were strong enough to do so. The Turks themselves were too much occupied elsewhere to pay much attention to the Danubian principalities till the middle of the 15th century. In 1478 Mahomet II. had indeed attempted their subjugation, with but indifferent success; but it was not till 1484 that the Ottomans became inconvenient neighbours to Poland. In that year a Turkish fleet captured the strongholds of Kilia and Akkerman, commanding respectively the mouths of the Danube and Dniester. This aggression seriously threatened the trade of Poland, and induced Casimir IV. to accede to a general league against the Turks. In 1485, after driving the Turks out of Moldavia, the Polish king, at the head of 20,000 men, proceeded to Kolomea on the

Poland

30th, where Bayazid II., then embarrassed by the Egyptian war, offered peace, but as no agreement concerning the captured fortresses could be arrived at, hostilities were suspended by a truce. During the remainder of his reign the Turks gave no trouble.

It was a fortunate thing for Poland that, during the first century of her ascension to the rank of a great power, political exigencies compelled her to appropriate almost more territory than her primitive and centrifugal government could properly assimilate; it was fortunate that throughout this period of expansion her destines should, with one brief interval, have been controlled by a couple of superior statesmen, each of whom ruled for nearly fifty years. During the fourteen years (1492-1506) which separate the reigns of Casimir IV. and Sigismund I. she was not so fortunate. The controlling hand of Casimir IV. was no sooner withdrawn than the unruly elements, ever present in the Republic, and ultimately the cause of its ruin, at once burst forth. The first symptom of this lawlessness was the separation of Poland and Lithuania, the Lithuanians proceeding to elect Alexander, Casimir's fourth son, as their grand-duke, without even consulting the Polish senate, in flagrant violation of the union of Horodło. The breach, happily, was of no very long duration. A disastrous war with Ivan III., the first Muscovite tsar, speedily convinced the Lithuanians that they were not strong enough to stand alone, and in 1499 they voluntarily renewed the union. Much more dangerous was the political revolution proceeding simultaneously in Poland, where John Albert, the third son of Casimir, had been elected king on the death of his father. The nature of this revolution will be considered in detail when we come to speak of the growth of the Polish constitution. Suffice it here to say that it was both anti-monarchical and anti-democratic, tending, as it did, to place all political authority in the hands of the szlachta, or gentry. The imprecocious monarch submitted to the dictate of the diet in the hope of obtaining sufficient money to prosecute his ambitious designs. With his elder brother Władislaus reigning over Bohemia and Hungary the credit of the Jagiellons in Europe had never been so great as it was now, and John Albert, bent upon military glory, eagerly placed himself at the head of what was to have been a great anti-Turkish league, but ultimately dwindled down to a raid upon Moldavia which ended in disaster.

The sole advantage which John Albert reaped from his chieftainship of the Christian cause was the favour of the Curia, and the ascendancy which that favour gave him over the Teutonic Knights, whose new grand-master, Albert of Saxony, was reluctantly compelled to render due homage to the Polish king.

Under Alexander (q.v.), who succeeded his brother in 1501, matters went from bad to worse. Alexander's election cemented, indeed, once for all, the union between Poland and Lithuania, inasmuch as, on the eve of it (Oct. 3, 1501) the senates of both countries agreed that, in future, the king of Poland should always be grand-ducé of Lithuania; but this was the sole benefit which the Republic derived from the reign of Alexander, under whom the Polish government had been well described as a rudderless ship in a stormy sea, with nothing but the grace of God between it and destruction. In Lithuania the increasing pressure of the Muscovite was the chief danger. Till the accession of Ivan III. in 1462 Muscovy had been a negligible factor in Polish politics. During the earlier part of the 15th century the Lithuanian princes had successfully contested Muscovite influence even in Pskov and Great Novgorod. Many Russian historians even maintain that, but for the fact that Witowt had simultaneously to cope with the Teutonic Order and the Tatars, that energetic prince would certainly have extinguished struggling Muscovy altogether. But since the death of Witowt (1430) the military efficiency of Lithuania had sensibly declined; single-handed she was no longer a match for her ancient rival. This was owing partly to the evils of an oligarchic government; partly to the weakness resulting from the natural attraction of the Orthodox-Greek element in Lithuania towards Muscovy, especially after the fall of Constantinople, but chiefly to the administrative superiority of the highly centralized Muscovite government. During the reign of Alexander IV. the king of Lithuania had to depend upon an army in Lithuania, the Muscovites and Tatars ravaged the whole country at will, and were prevented from conquering it altogether only by their inability to capture the chief fortresses.

In Poland, meanwhile, something very like anarchy prevailed. Alexander had practically surrendered his authority to an incapable aristocracy, whose sole idea of ruling was systematically to oppress and humiliate the lower classes. In foreign affairs a policy of drift prevailed which encouraged all the enemies of the Republic to raise their heads, while the dependent states of Prussia in the north and Moldavia in the south made strenuous efforts to break away from Poland. Fortunately for the integrity of the Polish state the premature death of Alexander in 1506 brought upon the throne his capable brother Sigismund, the first son of Casimir IV., whose long reign of forty-two years was salutary, and would have been altogether recuperative, had his statesmanship only been loyally supported by his subjects. Eminentiy practical, Sigismund recognized that the first need of Poland was a standing army. The miserable collapse of the Polish chivalry during the Bukovian campaign of 1497 had convinced every one that the russeńcę pospolite was useless for serious military purposes, and that Poland, in order to hold her own, must in future follow the example of the West, and wage her warfare with trained mercenaries. But professional soldiers could not be hired without money, and the difficulty was to persuade the diet to loose its purse-strings. All that the gentry contributed at present was two pence (groschen) per head of land, and this only for defensive service at home. If the king led the russeńcę pospolite abroad he was obliged to pay so much per pike out of his own pocket, notwithstanding the fact that the heavily mortgaged crown lands were practically valueless. At the diet of 1510 the chancellor and privy, Adam Laski, proposed an income-tax of 50% at once, and 5% for subsequent years, payable by both the lay and clerical estates. In view of the fact that Poland was the most defenceless country in Europe, with no natural boundaries, and constantly exposed to attacks from every quarter, it was not unreasonable to expect even this patriotic sacrifice from the privileged classes, who held at least two-thirds of the land by military tenure. Nevertheless, the diet refused to consider the scheme. In the following year a more modest proposal was made by the Crown in the shape of a capitation of six gulden, to be levied on every nobleman at the beginning of a campaign, for the hiring of mercenaries. This also was rejected. In 1512 the king came forward with a third scheme. He proposed to divide the country into five circles, corresponding to the five provinces, each of which was to undertake to defend the realm in turn should occasion arise. Moreover, every one who so desired it might pay a commutation in lieu of personal service, and the amount so realized was to be re-used to levy troops. To this the dietics, or local diets, of Great Poland, and Little Poland, agreed, but at the last moment the whole project founded on the question who was the proper custodian of the new assessment rolls, and the king had to be content with the renewal of former subsidies, varying from twelve to fifteen groats per head of land for three years. Well might the disappointed monarch exclaim: “It is vain to labour for the welfare of those who do not care a jot about it themselves.” Matters improved somewhat in 1527, when the szlachta, by a special act, placed the mightiest magnates on the same level as the humblest squire as regards military service, and proposed at the same time a more general assessment for the purpose, the control of the money so realized to be placed in the hands of the king. In consequence of this law the great lords were compelled to put forces in the field proportioned to their enormous fortunes, and Sigismund was able in 1529 to raise 300 foot and 3200 horse from the province of Podoll alone. But though the treasury was thus temporarily replenished and the army increased, the gentry who had been so generous at
the expense of their richer neighbours would hear of no additional burdens being laid on themselves, and the king only obtained what he wanted by sacrificing his principles to his necessities, and helping the szlachta to pull down the magnates. This fatal parsimony had the most serious political consequences, for it crippled the king's capacity to defend the state in any emergency. My only point of view was that he might, his needs were so urgent, his enemies so numerous, that, though generally successful in the end, he had always to be content with compromises, adjustments and semi-victories. Thus he was obliged, in 1525, to grant local autonomy to the province of Prussia instead of annexing it; he was unable to succour his unfortunate nephew, Louis of Hungary, against the Turkish peril; he was compelled to submit to the occupation of one Lithuanian province after the other by the Muscovites, and look on helplessly while myriads of Tatars penetrated to the very heart of his domains, wasting with fire and sword everything they could not carry away with them.

Again, it should have been the first duty of the Republic adequately to fortify the ąskile pole, or “savage steppe,” as the vast plain was called which extended from Kiev to the Black Sea, and some feeble attempts to do so were at last made. Thus, in the reign of Alexander, the fugitive serfs whom tyranny or idleness had driven into this wilderness (they were subsequently known as Kazaki, or Cossacks, a Tartar word meaning freebooters) were formed into companies (c. 1504) and placed at the disposal of the frontier starostas, or lord marchers, of Kaniev, Kamencets, Czerekask on the Don and other places. But these measures proved inadequate, and in 1533 the lord marcher, Ostaf Dzaskiewicz, the hero of Kaniev, which he had successfully defended against a countless host of Turks and Tatars, was consulted by the diet as to the best way of defending the Ukraine permanently against such inroads. The veteran expert advised the populating and fortifying of the islands of the Dnieper. Two thousand men would suffice, he said, and the Cossacks supplied excellent military material ready to hand. The diet unanimously approved of this simple and inexpensive plan; a special commission examined and approved of its details, and it was submitted to the next diet, which rejected it. So nothing at all was done officially, and the defence of the eastern Ukraine was left to private enterprise. Oddly enough the selfish prudence of Sigismund was rewarded, Queen Barbara, a more enterprising and far-sighted defence than the Polish state could do. Thus, to defend her immense possessions in Volhynia and Podolia, she converted the castles of Bar and Kremieniecko into first-class fortresses, and placed the former in the hands of her Silesian steward, who acquitted himself so manfully of his charge that “the Tatars fell away from the frontier all the days of Pan Prełecz,” and a large population settled securely beneath the walls of Bar, henceforth known as “the bastion of Podolia.” Nothing, perhaps, illustrates so forcibly the casual character of the Polish government in the most vital matters as this single incident.

The most important political event during the reign of Sigismund was the collapse of the ancient Hungarian monarchy at Mohacs in 1526. Poland, as the next neighbour of Hungary, was much more seriously affected than any other European power by this catastrophe, but her politicians differed as to the best way of facing it. Immediately after the death of King Louis, who fell on the field of battle, the emperor Ferdinand and John Zapolya, voivode of Transylvania, competed for the vacant crown, and both were elected almost simultaneously. In Poland Zapolya’s was the popular cause, and he also found powerful support in the influential and highly gifted Laski family, as represented by the Polish chancellor and his nephews John and Hieronymus. Sigismund, on the other hand, favoured Ferenc Habsburg, the archduke. Though bound by family ties with both competitors, he regarded the situation from a purely political point of view. He argued that the best way to keep the Turk was for Poland to be annexed by Hungary, in which case the Austrian dominion would be a strong and permanent barrier against a Muselman invasion of Europe. This was one of the main reasons why the Emperor, and his brother the archduke, were opposed to the marriage of Sigismund and Barbara, which would have restored Hungary to the house of Anjou.

1 Prełecz won no fewer than 70 engagements over the Tatars.

More than justified him, and the long duel which ensued between Ferdinand and Zapolya (see Hungary: History) enabled the Polish monarch to maintain to the end a cautious but observant neutrality. More than once, indeed, Sigismund was seriously compromised by the diplomatic vagaries of Hieronymus Laski, minister of the service of Zapolya (since 1529 the creștescu of the sultan), and greatly alarmed both the emperor and the pope by his disturbing philo-Turk proclivities. It was owing to Laski’s intrigues that the new hospodar of Moldavia, Petrylo, after doing homage to the Porte, intervened in the struggle as the foe of both Ferdinand and Sigismund, and besieged the Grand Hetman of the Crown, Jan Tarnowski, in Obertyn, where, however, the Moldavians (August 22, 1531) sustained a crushing defeat, and Petryloy was slain. Nevertheless, so anxious was Sigismund to avoid a collision with the Turks, that he forbade the victorious Tarnowski to cross the Moldavian frontier, and sent a letter of explanation to Constantinople. On the death of John Zapolya, the Austro-Polish alliance was still further cemented by the marriage of Sigismund’s son and heir, Sigismund Augustus, with the archduchess Elizabeth. In the reign of Sigismund was effected the incorporation of the duchy of Masovia with the Polish crown, after an independent existence of five hundred years. In 1526 the male line of the ancient dynasty became extinct, and on the 26th of August Sigismund received the homage of the Masovians at Warsaw, the capital of the duchy and ere long of the whole kingdom. Almost every acre of densely populated Masovia was in the hands of her sturdy, ultra-conservative squires, in point of culture far below their brethren in Great and Little Poland. The additional revenue gained by the Crown from Masovia was at first but 14,000 gulden per annum.

The four and twenty years of Sigismund II’s reign was a critical period of Polish history. Complications with the Turk were avoided by the adroit diplomacy of the king, while the superior discipline and efficiency of the Polish armies under the great Tarnowski (q.v.) and his pupils overawed the Tatars and extruded the Muscovites, neither of whom were so troublesome as they had been during the last reign. All the more disquieting was the internal condition of the country, due mainly to the invasion of Poland by the Reformation, and the coincidence of this invasion with an internal revolution of a character resembling that which had already substituted the rule of the szlachta for the rule of the senate.

Hitherto the Republic had given the Holy See but little anxiety. Hussite influences, in the beginning of the 15th century, had been superficial and transient. The Polish government had employed Hussite mercenaries, but rejected Hussite propagandists. The edict of Wielun (1424), remarkable as the first anti-heretical decree issued in Poland, crushed the new sect in its infancy. Lutheranism, moreover, was at first regarded with grave suspicion by the intensely patriotic Polish gentry, because of its German origin. Nevertheless, the extremely severe penal edicts issued during the reign of Sigismund II., though seldom applied, seem to point to the fact that heresy was spreading widely throughout the country. For a time, therefore, the Protestants had to be cautious in Poland proper, but they found a sure refuge in Prussia, where Lutheranism was already the established religion, and where the newly erected university of Königsberg became a seminary for Polish ministers and preachers.

While Lutheranism was thus threatening the Polish Church from the north, Calvinism had already invaded her from the west. Calvinism, indeed, rather recommended itself to the Poles as being of non-German origin, and Calvin actually dedicated his Commentary on the Mass to the young Arnet (or crown prince) Sigismund Augustus, from whom protestantism, sufficiently enough, expected much in the future. Meanwhile conversion to Calvinism, among the higher classes in Poland, became more and more frequent. We hear of crowded Calvinist conventicles in Little Poland from 1545 onwards, and Calvinism continued to spread throughout the kingdom during the latter
years of Sigismund I. Another sect, ultimately found even more favour in Poland than the Calvinists, was that of the Bohemian Brethren. We first hear of them in Great Poland in 1548. A royal decree promptly banished them to Prussia, where they soon increased so rapidly as to be able to hold their own against the Lutherans. The death of the uncompromising Sigismund I. came as a great relief to the Protestants, who entertained high hopes of his son and successor. He was known to be familiar with the works of the leading reformers; he was surrounded by Protestant counsellors, and he was actually married to Barbara, daughter of Prince Nicholas Radziwill, "Black Radziwill," the all-powerful chief of the Lithuanian Calvinists. It was not so generally known that Sigismund II. was by conviction a sincere though not a bigoted Catholic; and nobody suspected that beneath his diplomatic urbanity lay a patriarchal firmness and statesmanlike qualities of the first order. Moreover, they ignored the fact that the success of the Protestant propaganda was due rather to political than to religious causes. The Polish gentry's jealousy of the clerical estate, whose privileges even exceeded their own, was at the bottom of the whole matter. Any opponent of the established clergy was the natural ally of the szlachta, and the scandalous state of the Church herself provided them with a most formidable weapon against her. It is not too much to say that the condition of the Catholic Church in Poland was almost as bad as it was in Scotland during the same period. The bishops were, for the most part, elegant triflers, as pliant as reeds, with no fixed principles and saturated with a false humanism. Some of them were notorious evil-livers. "Pint-pot" Latuski, bishop of Posen, had purchased his office for 12,000 ducats from Queen Bona; while another of her creatures, Peter, popularly known as the "wrencher," was appointed bishop of Przemysl with the promise of the reversion of the still richer see of Cracow. Moreover, despite her immense wealth (in the province of Little Poland alone she owned at this time 26 towns, 83 landed estates and 772 villages), the Church claimed exemption from all public burdens, from all political responsibilities, although her prelates continued to exercise an altogether disproportionate political influence. Education was shamefully neglected, the masses being left in almost heathen ignorance—and this, too, at a time when the upper classes were greedily appropriating the ripe fruits of the Renaissance and when, to use the words of a contemporary, there were "more Latins in Poland than there used to be in Latium." The university of Cracow, the only Paris of Poland, was outdistanced in the vicious circle of scholastic formularies. The provincial schools, dependent upon so decrepit an alma mater, were suffered to decay. This criminal neglect of national education brought along with it its own punishment. The sons of the gentry, denied proper instruction at home, betook themselves to the nearest universities across the border, to Goldberg in Silesia, to Wittenberg, to Leipzig. Here they fell in with the adherents of the new faith, grave, earnest men who professed to reform the abuses which had grown up in the Church; and a sense of equity as much as a love of novelty moved them, on their return home, to propagate wholesome doctrines and clamour for the reformation of their own. From the very walls of Poland, as it were, the gentry and szlachta against their own spiritual rulers and eagerly devoured and imparted to their flocks, in their own language, the contents of the religious tracts which reached them by divers ways from Goldberg and Königsberg. Nothing indeed did so much to popularize the new doctrines in Poland as this beneficial revival of the long-neglected vernacular by the reformers.

Such was the situation when Sigismund II. began his reign. The bishops at once made a high bid for the favour of the new king by consenting to the coronation of his Calvinist consort (Dec. 7, 1550) and the king five days later to receive a Cromwellian edict (March 1551) whereby he pledged his royal word to preserve intact the unity of the Church and to enforce the law of the land against heresy. Encouraged by this pleasing sympton of orthodoxy the bishops, instead of first attempting to put their own dilapidated house in order, at once proceeded to institute prosecutions for heresy against all and sundry. This at once led to an explosion, and at the diet of Piotrkow, 1552, the szlachta accepted a proposition of the king, by way of compromise, that the jurisdiction of the clerical courts should be suspended for twelve months, on condition that the gentry continued to pay tithes as heretofore. Then began a religious interim, which was gradually prolonged for ten years, during which time Protestantism in Poland flourished exceedingly. Presently reformers of every shade of opinion, even those who were tolerated nowhere else, poured into Poland, which speedily became the battle-ground of all the sects of Europe. Soon the Protestants became numerous enough to form ecclesiastical districts of their own. The first Calvinist synod in Poland was held at Pinczow in 1550. The Bohemian Brethren evangelized Little Poland, but ultimately coalesced with the Calvinists at the synod of Kozminice (August 1555). In the diet itself the Protestants were absolutely supreme, and invariably elected a Calvinist to be their marshal. At the diet of 1555 they boldly demanded a national synod, absolute toleration, and the equalization of all the sects except the Anti-trinitarians. But the king intervened and the existing interim was indefinitely prolonged. At the diet of Piotrkow, 1558–1559, the onslaught of the szlachta on the clergy was fiercer than ever, and they even demanded the exclusion of the bishops from the senate. The king, however, perceiving a danger to the constitution in the violence of the szlachta, not only supported the bishops, but quashed a subsequent reiterated demand for a national synod. The diet of 1558–1559 indicates the high-water mark of Polish Protestantism. From this time forward it began to subside, very gradually but unmistakably. The chief cause of this subsidence was the division among the reformers themselves. From the chaos of creeds resulted a chaos of ideas on all imaginable subjects, politics included. The Anti-trinitarian proved to be the chief dissolvent, and from 1560 onwards the relations between the two principal Protestant sects, the Lutherans and the Calvinists, were fratricidal rather than fraternal. An auxiliary cause of the decline of Protestantism was the beginning of a Catholic reaction. The bulk of the population still held persistently, if languidly, to the faith of its fathers; the new bishops were holy and learned men, very unlike the creations of Queen Bona, and the Holy See gave to the slowly reviving zeal of both clergy and laity the very necessary stimulus. Finally, Sigismund, who had been unfortunately, in those days of difficult inter-communication, not too far off, and it is indisputable that in the first instance it was the papal nuncios, men like Berard of Camerino and Giovanni Commedone, who reorganized the scattered and faint-hearted battalions of the Church militant in Poland and led them back to victory. At the diet of Piotrkow in 1562, indeed, the king's sore need of subsidies induced him, at the demand of the szlachta, to abolish altogether the jurisdiction of the ecclesiastical courts in cases of heresy; but, on the other hand, at the diet of 1564 he accepted from Commedone the Tridentine decrees and issued an edict banishing all foreign, and especially Anti-trinitarian, heretics from the land. At the diet of 1565 Sigismund went too far. He exiled the entire Calvinist clergy and pronounced the pacificatory synod as unnecessary, inasmuch as the council of Trent had already settled all religious questions, and at the same time consented to the Counter-Reformation in Poland.
of January 1569. But even now the Lithuanians were indisposed towards a complete union, and finally they quitted the diet, leaving two commissioners behind to watch their interests. Then Sigismund executed his master stroke. Knowing the sensitiveness of the Lithuanians as regards Volhynia and Podolia, he suddenly, of his own authority, formally incorporated both these provinces with the kingdom of Poland, whereupon, amidst great enthusiasm, the Volhynian and Podolian deputies took their places on the same benches as their Polish brethren. The hands of the Lithuanians were forced. Even a complete union on equal terms was better than mutilated independence. Accordingly they returned to the diet, and the union was unanimously adopted on the 1st of July 1569. Henceforth the kingdom of Poland and the grand duchy of Lithuania were to constitute one inseparable and indivisible body politic, under one sovereign, elected in common, with one diet and one currency. All dependencies and colonies, including Prussia and Livonia, were to belong to Poland and Lithuania in common. The retention of the old duality of dignities was the one reminiscence of the original separation. No decision, however, could be come to as to the successor of the childless king, partly because of the multiplicity of candidates, partly because of Austrian intrigue, and this, the most momentous question of all, was still unsettled when Sigismund II. expired on the 6th of July 1572.

The Jagiellonic period (1386-1572) is the history of the consolidation and fusion into one homogeneous, political whole of numerous national elements, more or less akin ethnologically, but differing immensely in language, religion and, above all, in degrees of civilization. Out of the ancient Fiast kingdom, mutilated by the loss of Silesia and the Baltic shore, arose a republic consisting at first of various loosely connected entities, naturally centrifugal, but temporarily drawn together by the urgent need of combination against a superior foe, who threatened them separately with extinction. Beneath the guidance of a dynasty of princes which, curiously enough, was supplied by the least civilized portion of this congeries of nationalities, the nascent republic gradually grew into a power which substituted its former oppressors and, viewed externally, seemed to bear upon it the promise of empire. It is dangerous to prophesy, but all the facts and circumstances before us point irresistibly to the conclusion that had the Jagiellonic dynasty but endured this promise of empire might well have been realized. The extraordinary thing about the Jagiellows was the equable persistency of their genius. Not only were five of the seven great statesmen, but they were statesmen of the same stamp. We are disturbed by no such sharp contrasts as are to be found among the Plantagenets, the Vassas and the Bourbons. The Jagiellows were all of the same mould and pattern, but the mould was a strong one and the pattern was good. Their predominant and constant characteristic is a sober sagacity which instinctively judges aright and imperturbably realizes its inspirations. The Jagiellows were rarely brilliant, but they were always perspicacious. Above all, they alone seem to have had the gift of guiding the most difficult of nations properly. Two centuries of Jagiellon rule made Poland great despite her grave external difficulties. Had that dynasty been prolonged for another century, there is every reason to suppose that it would also have dealt satisfactorily with Poland's still more dangerous internal difficulties, and arrested the development of that anarchical constitution which was the ruling factor in the ruin of the Republic.

Simultaneously with the transformation into a great power of the political principles which composed ancient Poland, another and equally momentous political transformation was proceeding within the country itself.

The origin of the Polish constitution is to be sought in the wice or councils of the Polish princes, during the partitional period (c. 1270-1370). The privileges conferred upon the magnates of which these councils were composed, especially upon the magnates of Little Poland, who brought the Jagiellows to
the throne, directed their policy, and grew rich upon their
liberality, revoked the less favoured szlachta, or gentry, who,
towards the end of the 14th century, combined for
mutual defence in their sejmiki, or local diets, of which originally there were five, in three in Great
Poland, one in Little Poland and one in Posen-Kalisz. In
these sejmiki, the diets of the few great towns were also
represented. The Polish towns not in Cracow, Gdansk, and
their privileges, including freedom from tolls and municipal
government, from the Crown in return for important
services, such as warding off the Tatars, while the cities of German
origin were protected by the Magdeburg law. Casimir
Great even tried to make municipal government as democratic
as possible by enacting that one half of the town council of
Cracow should be elected from the civic patriciate, but the
other half from the commonalty. Louis the Great placed the
burgesses on a level with the gentry by granting to the town
council of Cracow jurisdiction over all the serfs in the extra-
local estates of the citizens. From this time forth deputies from the
cities were summoned to the sejmiki on all important occasions,
such, for instance, as the ratification of treaties, a right formally
ceded to them by the sejmik of Radom in 1384. Thus at
this period Poland was a confederation of half a dozen semi-
independent states. The first general assembly of which we
have certain notice is the szat walny which was summoned to
Kozyce in November 1404, to relieve the financial embarrass-
ments of Wladislaus, and granted him an extraordinary subsidy
of twenty groats per head of land to enable him to purchase
Dobrzyń from the Teutonic Knights. Such subsidies were
thereafter the price for the confirmation of ancient or the
concession of new privileges. Thus at the diet of Brzézki Kaszawski,
in 1425, the szlachta obtained its first haseb corpus act in return
for acknowledging the right of the infant krolowica Wladislaus
to his father’s throne. The great opportunity of the szlachta
was, of course, the election of a new king, especially the election
of a minor, an event always accompanied and succeeded by
disturbances. Thus on the election of the infant Wladislaus III.,
his guardians promised in his name to confirm all the privileges
granted by his father. If, on attaining his majesty, the king
refused to ratify these promises, his subjects were ipso facto
absolved from their obedience. This is the first existence of the
mischiefous principle de pretandi oedebientia, subsequently
elementary in Polish law. It is a principle that we meet
with the first rokosz, or insurrection of the szlachta against
the executive. The extraordinary difficulties of Casimir IV were
freely exploited by the szlachta, who granted that over impune-
rious monarch as little as possible, but got full value for every
penny they grudgingly gave. Thus by the Articles of Cerekwica
presented to him by the sejmik or diet of Great Poland in
1454 on the outbreak of the Teutonic War, he conceded the
principle that no war should in future be begun without the
consent of the local diets. A few months later he was obliged
to grant the Privileges of Nieszawa, which confirmed and
extended the operation of the Articles of Cerekwica. The
sejmik had thus added to their original privilege of self-taxation
the right to declare war and even to fight it. It was a
serious political retrogression. A strongly centralized
government had ever been Poland’s greatest need, and Casimir
the Great had striven successfully against all centrifugal
tendencies. And now, eighty-four years after his death, Poland
was once more split up into half a dozen loosely federated states
in the hands of country gentlemen too ignorant and prejudiced
to look beyond the boundaries of their own provinces.
The only way of saving the Republic from disintegration was to
concentrate all its political factors into a sejm-walny or general
diet. But to this the magnates and the szlachta were equally
opposed, the former because they feared the rivalry of a national
assembly, the latter because there were of more importance
in their local diets than they could possibly hope to be in a
general diet. The first sejm to legislate for the whole of Poland
was the diet of Piotrkov (1493), summoned by John Albert
to grant him subsidies; but the mandates of its deputies were
limited to twelve months, and its decrees were to have force
for only three years. John Albert’s second diet (1496), after
granting subsidies the burden of which fell entirely on the
towns and peasantry, passed a series of statutes benefiting
the towns. One of these, the szlachta clause, was the same as
the one in the earlier sejm which had permitted the
slaughter hencethrough to export an important
goodstofreely, to the great detriment of the towns and
the treasury. Another statute prohibited the burgesses from
holding landed property and enjoying the privileges attaching thereto.
A third statute disqualified plebeians from being elected
to canons or bishops. A fourth endeavoured to bind the
peasantry more closely to the soil by forbidding emigration.
The condition of the serfs was subsequently (1520) still further
deteriorated by the introduction of socage. In a word, this
diet disturbed the equilibrium of the state by enfeebling and
degrading the middle classes. Nevertheless, so long as the
Jagiellod dynasty lasted, the political rights of the cities were
jealously protected by the Crown against the usurpations of
the nobility. Deputies from the towns took part in the election
of John Albert (1492), and the burgesses of Cracow, the most
enlightened economists in the kingdom, supplied Sigismund I.
with his most capable councillors during the first twenty years
of his reign (1566-1566). Again and again the nobility attempted
to exclude the deputies of Cracow from the diet, in spite of
a severe edict issued by Sigismund I. in 1509, threatening to
prosecute for treason all persons who dared to infringe the
liberties of the citizens. During Sigismund’s reign, moreover,
the Crown recovered many of the prerogatives of which it had
been deprived during the reign of his feeble predecessor, Alex-
ander, who, to say nothing of the curtailments of the prerogative,
was no longer the effective master of the nobility. The
childless Sigismund II. died suddenly without leaving any
regulations as to the election of his successor. Fortunately
for Poland the political horizon was absolutely
unucloulded. The Turks, still reeling from the shock
of Lepanto, could with difficulty hold their own
against the united forces of the pope, Spain and Venice;
while Ivan the Terrible, had just concluded a truce with
Poland. Domestic affairs, on the other hand, were in an almost
anarchical condition. The Union of Lublin, barely three
years old, was anything but consolidated, and in Lithuania
it continued to be extremely unpopular. In Poland proper
the szlachta continued to enjoy privileges which were never
enjoyed in the country, assembled at Warsaw, in April 1573,
for the purpose of electing a new king. Five candidates for the throne were already in the field. Lithu-
ania favoured Ivan IV. In Poland the bishops and most of

1 The Red Russian sejmik was of later origin, c. 1433.
2 In view of the frequency of the Tatar invasions, the control of
the militia was re-transferred to the Crown in 1501.
the Catholic magnates were for an Austrian archduke, while the strongly anti-German szlachta were inclined to accept almost any candidate but a German, so long as he came with a gift in his hand and was not a Muscovite. In these circumstances it was an easy task for the adroit and energetic French ambassador, Jean de Montluc (d. 1579), brother of the famous marshal, and bishop of Valence, to procure the election of the French candidate, Henry, duke of Anjou. Well provided with funds, he speedily bought over many of the leading magnates, and his popularity reached its height when he strenuously advocated the adoption of the mode of election by the gentry en masse (which the szlachta proposed to revive), as opposed to the usual and more orderly "secret election" by a congress of senators and deputies, sitting with closed doors. The religious difficulty, meanwhile, had been adjusted to the satisfaction of all parties by the compact of Warsaw (Jan. 28, 1573), which granted absolute religious liberty to all non-Catholic denominations (dissidentes de religione, as they now began to be called) without exception, thus exhibiting a far more liberal intention than the Germans had manifested in the religious peace of Augsburg eighteen years before. Finally, early in April 1573, the election diet assembled at Warsaw, and on the 11th of May, in the midst of intrigue, corruption, violence and confusion, Henry of Valois was elected king of Poland.

The election had, however, been preceded by a correctura jurum, or reform of the constitution, which resulted in the famous "Henrican Articles" which converted Henry of Valois, king of Poland from a limited monarchy into a republic 1573-1574. with an elective chief magistrate. Henceforward the king was to have no voice in the choice of his successor. He was not to use the word haeres, not being an hereditary sovereign. He was to marry a wife selected for him by the senate. He was neither to seek for a divorce nor give occasion for one. He was to be neutral in all religious matters. He was not to lead the militia across the border except with the consent of the szlachta, and then only for three months at a time. Every year the senate was to appoint sixteen of its number to be in constant attendance upon the king in rotas of four, which selectimuris were to supervise all his actions. Should the king fail to observe any one of these articles, the nation was ipso facto absolved from its allegiance. This constitutional reform was severely criticized by contemporary political experts. Some strongly condemned the clause justifying renunciation of allegiance, as tending to treason and anarchy. Others pointed against the anomalous and helpless position of the so-called king, who, if he could do no harm, was certainly powerless for good. But such Cassandra's prophesied to heedless ears. The Republic had deliberately cast itself upon the downward grade which was to lead to ruin.

The reign of Henry of Valois lasted thirteen months. The tidings of the death of his brother Charles IX., which reached him on the 14th of June 1574, determined him to exchange a thorny for what he hoped would be a flowery throne, and at midnight on the 18th of June 1574 he literally fled from Poland, pursued to the frontier by his indignant and bewildered subjects. Eighteen months later (Dec. 14, 1575), mainly through the influence of Stephen Báthory, prince of Transylvania, was elected king of Poland by the szlachta in opposition to the emperor Maximilian, who had been elected two days previously by the senate, after disturbances which would have rent any other state but Poland to pieces.

The glorious career of Stephen Báthory (1575-1586) is dealt with elsewhere (see STEPHEN, KING OF POLAND). His example demonstrates the superiority of genius and valour over the most difficult circumstances. But his reign was too brief to be permanently beneficial.

The Vasa period of Polish history which began with the election of Sigismund, son of John III., king of Sweden, was the epoch of peace and glory, and the last chance. The collapse of the Muscovite tsardom in the east, and the submission of the German Empire in the west by the Thirty Years' War, presented Poland with an unpreceded opportunity of consolidating, once for all, her hard-won position as the dominating power of central Europe. Everywhere circumstances were favourable to her, and in Żółkiewski, Chodkiewicz and Koniecpolski she possessed three of the greatest captains of that or any other age. With all the means at her disposal cheerfully placed in the hands of such valiant and capable ministers, it would have been no difficult task for the Republic to have wrested the best part of the Baltic littoral from the Scandinavian powers, and driven the distracted Muscovites beyond the Volga. Permanent greatness and secular security were within her reach at the commencement of the Vasa period; how was it, then, that at the end of that period, only fifty years later, Poland had already sunk irredeemably into much the same position as Turkey occupies now, the position of a moribund state, existing on sufferance simply because none was yet quite prepared to administer the coup de grâce? There is only one answer; the principal cause of this complete and irretrievable collapse is to be sought for in the folly, egotism and selfishness of the Polish gentry, whose insane dislike of all discipline, including even the salutary discipline of regular government, converted Poland into something very like a primitive tribal community at the very time when civil and European statesman, including the more enlightened of the Poles themselves, clearly recognized that the political future belonged to the strongly centralized monarchies, which were everywhere rising on the ruins of feudalism. Of course there were other contributory causes. The tenacity with which Sigismund III. clung to his hereditary rights to the Swedish Crown involved Poland in a quite unnecessary series of wars with Charles IX. and Gustavus Adolphus, when her forces were sorely needed elsewhere. The adhesion of the same monarch to the League of the Catholic Reaction certainly added to the difficulties of Polish diplomacy, and still further divided the already distracted diet, besides alienating from the court the powerful and popular chancellor Zamorski. Yet Sigismund III. was a far more clear-minded statesman than any of his counsellors or contradicators. For instance, he was never misled by the successes of the false Demetrius in Muscovy, and wisely insisted on recovering the great eastern fortress of Smolensk rather than attempting the conquest of Moscow. His much-decried alliance with the emperor at the outbreak of the Thirty Years' War was eminently sagacious. He perceived at once that it was the only way of counteracting the restlessness of the sultan's protégés, the Protestant princes of Transylvania, whose undisobedient horses, scarcely less savage than their allies the Turks and Tatars, were in peril of rending the frame of the Polish monarchy. And he was also further divested of the temporary and pernicious subsidies, they saw to it that such subsidies should rest entirely on the shoulders of the burgesses (who had in the meantime been deprived of the franchise) and the already overburdened peasantry. In the very crisis of the Swedish War, the diminutive army of the victorious Chodkiewicz was left unpaid, with the result that the soldiers mutinied, and marched off en masse. Both Chodkiewicz and Żółkiewski frequently had to pay the expenses of their campaigns out of their own pockets, and were expected to conquer empires and defend hundreds of miles of frontier with armies of 3000 or 4000 men at most. When they retreated before overwhelming odds they were publicly accused of cowardice and incompetence. The determination to limit still further the power of the executive was at the bottom of this fatal paralysis, with the inevitable consequence that
while the king and the senate were powerless, everry great noble or lord-marcher was free to do what he chose in his own domains, so long as he flattered his “little brothers,” the szlachta. Incredibly as it may seem, the expedition to place the false Demetrius on the Muscovite throne was a private speculation of a few Lithuanian magnates, and similar enterprises on the part of other irresponsible noblemen on the Danube or Dniester borders of Poland were repeated for nearly two years longer, and was only terminated, in 1609, by a general amnesty which excluded every prospect of constitutional reform.

Wladislaus IV., who succeeded his father in 1632, was the most popular monarch who ever sat on the Polish throne. The szlachta, who had had a “King Log” in Sigismund, were determined that Wladislaus should be “a King Bee who will give us nothing but honey.”—1632-1648.

In other words they hoped to wheedle him out of even more than they had wrested from his predecessor. Wladislaus submitted to everything. He promised never to declare war or levy troops without the consent of the sejm, undertook to fill all vacancies within a certain time, and released the szlachta from the payment of income-tax, their one remaining fiscal obligation. This boundless complacency was due to policy, not weakness. The second Polish Vasa was a man of genius, fully conscious of his powers, and determined to use them for the benefit of his country. The events of the last reign had demonstrated the incompetence of the Poles to govern themselves. Any amelioration of the existing anarchy must be extra-parliamentary and proceed from the throne. But a reforming monarch was inconceivable unless he possessed the confidence of the nation, and such confidence, Wladislaus naturally argued, could only be won by striking and undeniable public services. On these principles he acted with brilliant results. Within three years of his accession he compelled the Muscovites (Treaty of Polyankova, May 28, 1634) to retrocede Smolensk and the eastern provinces lost by Sigismund II., overawed the Porte by a military demonstration in October of the same year, and, by the Truce of Stundorf (Sept. 12, 1635), recovered the Prussian provinces and the Baltic seaboard from Sweden. But these achievements excited not the gratitude but the suspicion of the szlachta. They were shrewd enough to guess that the royal triumph might prejudice their influence, and for the next five years they deliberately thwarted the enlightened and far-reaching projects of the king for creating a navy, and increasing the revenue by enforcing a customs’ and excise tax. By a system of duties levied on the trade of the Baltic ports (see Wladislaus IV.), even going so far as to refuse for nine years to refund the expenses of the Muscovite War, which he had defrayed out of his private purse. From sheer weariness and disgust the king refrained from any intervention in public affairs for nearly ten years, looking on indifferently while the ever shorter and stormier drills wrangled perpetually over questions of preferment and the best way of dealing with the extreme dissenters, to the utter neglect of public business. But towards the end of his reign the energy of Wladislaus revived, and he began to occupy himself with another scheme for regenerating his country, in its own despite, by means of the Cossacks. First, however, it is necessary to describe briefly the origin and previous history of these romantic free-booters who during the second half of the 17th century were the determining factor of Polish and Muscovite politics.

At the beginning of the 17th century the illimitable steppes of south-eastern Europe, extending from the Dnieper to the Ural, had no settled population. Hunters and fishermen frequented its innumerable rivers, returning home laden with rich store of fish and pelts, while runaway serfs occasionally settled in small communities beneath the shelter of the fortresses built, from time to time, to guard the southern frontiers of Poland and Muscovy. Obliged, for fear of the Tartars, to go about with arms in their hands, these settlers gradually grew strong enough to raid their raiders, selling the booty thus acquired to the merchants of Muscovy and Poland. Moreover, the Turks and Tatars being the natural enemies of Christendom, a war of extermination
against them was regarded by the Cossacks as a sacred duty. Curiously enough, these champions of orthodoxy borrowed the name, which has stuck to them ever since, from their "dog-headed" adversaries. The rank and file of the Tatar soldiery were known as Kazaki, or Cossacks, a word meaning "free-booters," and this term came to be applied indiscriminately to all the free dwellers in the Ukraine, or border-lands. As time went on, the Cossacks multiplied exceedingly. Their daring grew with their numbers, and at last they came to be a constant annoyance to all their neighbours, both Christian and Mussulman, frequently involving Poland in dangerous and unprofitable wars with the Ottoman Empire. Indeed, it is not too much to say that, until the days of Sobieski, the Cossacks were invariably the chief cause of the breaches between the Porte and the Republic. We have seen how carefully the Jagiellors avoided participating in any of the crusades directed by the Holy See against the arch-enemies of the Cross. So successful was their prudential abstention that no regular war occurred between Turkey and Poland during the two centuries of their sway. The first actual collisions, the Cecora campaign of 1620 and the Khotin War of 1621 (for John Albert's Moldavian raid does not count), were due to the depredations of the Cossacks upon the dominions of the sultan by land and sea, and in all subsequent treaties between the two powers the most essential clause was always that which bound the Republic to keep its freebooters in order.

But in the meantime the Cossacks themselves had become a semi-independent community. The origin of the Cossack state is still somewhat obscure, but the germs of it are visible as early as the beginning of the 16th century. The union of Lublin, which led to the polarization of Lithuania, was the immediate occasion of a considerable exodus to the lowlands of the Dnieper of those serfs who desired to escape from the taxes of the Polish government and the tyranny of the Polish landlords. Stephen Báthory presently converted the pick of them into six registered regiments of 1000 each for the defence of the border. Ultimately the island of Hortica, just below the falls of the Dnieper, was fixed upon as their headquarters, and on the numerous islands of that broad river there gradually arose the famous Cossack community known as the Zaporozhskaya Svyet, or Settlement behind the Falls, whence the Dnieperian Cossacks were known, generally, as Zaporozhians, or Backfallsmen. 1 The Cossack kosh, or commonwealth, had the privilege of electing its hetman, or chief, and his chief officers, the starshins. The hetman, after election, received from the escutcheon of Potem the insignia of his office, viz. the bulawa, or baton, the bunchuk, or horse-tail standard, and his official seal; but he was responsible for his actions to the kosh alone, and an inquiry into his conduct was held at the expiration of his term of office in the obshchaya shkoda, or general assembly. In time of peace his power was little more than that of the responsible minister of a constitutional republic; but in time of warfare he was a dictator, and disobedience to his orders in the field was punished by death.

The Cossacks were supposed to be left alone as much as possible by the Polish government, so long as they faithfully fulfilled their chief obligation of guarding the frontiers of the Republic from Tatar raids. But the relations between a community of freebooters, mostly composed of fugitive serfs and refugees, and a government of small squires who regarded the Cossacks as a mere rabble were bound to be difficult at the best of times, and political and religious differences presently supervened. The Cossacks, mostly of Lithuanian origin, belonged to the Orthodox religion, so far as they belonged to any religion at all, and the Jagiellors had been very careful to safeguard the religious liberties of their Lithuanian subjects, especially as the Poles themselves were indifferent on the subject. But, at the beginning of the 17th century, when the current of the Cossack republic ran very strongly to the West, the Jesuits, after subduing the Protestants, began to undermine the position of the Orthodox Church in Lithuania, a more intolerant spirit began to prevail. The old Calvinist nobility of Lithuania were speedily reconverted; a Uniate Church in connexion with Rome was established; Greek Orthodox congregations, if not generally persecuted, were at least depressed and straitened; and the Cossacks began to hate the Pans, or Polish lords, not merely as tyrants, but as heretics. Yet all these obstacles to a good understanding might, perhaps, have been surmounted if only the Polish diet had treated the Cossacks with common fairness and common sense. In 1619 the Polish government was obliged to prohibit absolutely the piratical raids of the Cossacks in the Black Sea, where they habitually destroyed Turkish property to the value of millions. At the same time, by the compact of Rastawica, the sejm undertook to allow the Cossacks, partly as wages, partly as compensation, 40,000 (raised by the compact of Kurukow to 60,000) gulden and 170 wagons of cloth per annum. These terms were never kept, despite the earnest remonstrances of the king, and the complaints of the aggrieved borderers. Parsimony prevailed, as usual, over prudence, and when the Cossacks showed unmistakable signs of restiveness, the Poles irritated them still further by ordering the construction of the strong fortress of Kudat at the confluence of the Dnieper and the Samara, to overawe the Zaporozhian community. This further act of repression led to two terrible Cossack risings, in 1635 and 1636, put down only with the utmost difficulty, whereupon the diet of 1638 deprived the Cossacks of all their ancient privileges, abolished the elective hetmanship, and substituted for it a commission of Polish noblemen with absolute power, so that the Cossacks might well declare that those who hated them were lords over them.

Such was the condition of affairs in the Ukraine when Wladislaus IV. proposed to make the Cossacks the pivot of his foreign policy and his domestic reforms. His far-reaching plans were based upon two facts, the absolute devotion of the Zaporozhians to himself personally, and the knowledge, secretly conveyed to him by Stanislaus Koniecpolski (q.v.), that the whole of the Ukraine was in a ferment. He proposed to provoke the Tartars to a rupture by repudiating the humiliating tribute with which the Republic had so long and so vainly endeavoured to buy off their incessant raids. In case of such rupture he meant, at the head of 100,000 Cossacks, to fall upon the Crimea itself, the seat of their power, and exterminate the Khanate. He calculated would bring about a retaliatory invasion of Poland by the Turks, who, instead of taking the field against them also with all the forces of the Republic, as he feared they would, would be able to impose the will of a victorious king upon a discredited diet, and reform the constitution on an English or Swedish model. Events seemed at first to favour this audacious speculation. Almost simultaneously a civil war broke out in the Crimea and the Porte declared war against the Venetian republic, with which Wladislaus at once concluded an offensive and defensive alliance (1645). He then bade the Cossacks prepare their boats for a raid upon the Turkish galleys, and secured the co-operation of the tsar in the Crimean expedition by a special treaty. Unfortunately, Venice, for her own petty selfish interests, published this agreement, and the Turks were alarmed. The Venetian alliance; the Porte, disapproving of the course of Polish affairs, remained strictly neutral despite the most outrageous provocations; and Wladislaus, bound by his coronation oath not to undertake an offensive war, found himself at the mercy of the diet which, full of consternation and rage, assembled at Warsaw on the 2nd of May 1647. It is needless to say that the Venetian alliance was repudiated and the royal power still further reduced. A year later Wladislaus died at his hunting-box at Merecz, at the very moment when the long-impending tempest which he himself had conjured up burst with overwhelming fury over the territories of the Republic.

Poland

unmasked and frustrated. To save himself he hit upon the novel and terrible expedient of uniting the Tatars and the Cossacks in a determined onslaught upon the Republic, whose inward weakness, despite its brilliant outward show, he had been quick to discern. On the 18th of April 1648, at the general assembly of the Zaporozhians, he openly expressed his intention of proceeding against the Poles and was elected hetman by acclamation; on the 19th of May he annihilated a small detached Polish corps on the banks of the river Zhelindya Vodot, and seven days later overwhemed the army of the Polish grand-hetman, massacring 800 of his 10,000 men and sending the grand-hetman himself and all his officers in chains to the Crimea. The immediate consequence of these victories was the outburst of a khlapekaya zloba, or "serfs' fury." Throughout the Ukraine the gentry were hunted down, flayed, burnt, blinded and sawn asunder. Every manor-house and castle was reduced to ashes. Every Uniate or Catholic priest who could be caught was hung up before his own high altar, along with a Jew and a hog. The panic-stricken inhabitants fled to the nearest strongholds, and soon the rebels were swarming over the palatinates of Volhynia and Podolia. Meanwhile the Polish army, 40,000 strong, under the command of the flimsiest general in the Cossack army, was bumbling on the frontiter. It consisted almost entirely of the noble militia, and was tricked out with a splendid more befitting a bridal pageant than a battle array. For Chmielnicki and his host these splendid cavaliers expressed the utmost contempt. "This rabble must be chased with whips, not smitten with swords," they cried. On the 23rd of September the two armies encountered near Pidlava, and after a stubborn three days' contest the gallant Polish pageant was scattered to the winds. The steppe for miles around was strewn with corpses; and the Cossacks are said to have reaped 100,000 guldens worth of booty when the fight was over. All Poland now lay at Chmielnicki's feet, and the road to the defenceless capital was open before him; but he wasted two precious months in vain before the fortress of Zamość, and then the newly elected king of Poland, John Casimir, Władysław IV's brother, privately opened negotiations with the rebel, officially recognized him by sending him the bulbaw and the other insignia of the hetman's dignity, and promised his "faithful Zaporozhians" the restoration of all their ancient liberties if they would break off their alliance with the Tatars and await the arrival of peace commissioners at Pereyaslav. But the negotiations at Pereyaslav came to nothing. Chmielnicki's coadjutors went to demand the surrender of the fortress of Durovicha; but the Polish army, the Cossack commanders durst not accept them, and in 1649 he again invaded Poland with a countless host of Cossacks and Tatars. Again, however, he made the mistake of attacking a fortress, which delayed his advance for a month, and gave John Casimir time to collect an army for the relief of the besieged. By the compact of Zborów (Aug 21, 1649) Chmielnicki was recognized as hetman of the Zaporozhians, whose registered number was now raised from 6,000 to 40,000; a general amnesty was also granted, and it was agreed that all official dignities in the Orthodox palatines of Lithuania should henceforth be held solely by the Orthodox gentry. For the next eighteen months Chmielnicki ruled the Russian provinces, and whenever he returned to his native place, the Cossack capital, subdivided the country into sixteen provinces, and entered into direct relations with foreign powers. His attempt to carve a principality for his son out of Moldavia led to the outbreak of a third war between suzerain and subject in February 1651. But fortune, so long Bohdan's friend, now deserted him, and at Beresteczko (July 1, 1651) the Cossack chieftain was utterly routed by Stephen Czarniecki. All hope of an independent Cossackdom was now at an end; yet it was not Poland but Muscovy which reaped the fruits of Czarniecki's victory.

Chmielnicki, by suddenly laying bare the nakedness of the Polish republic, had opened the eyes of Muscovy to the fact that her secular enemy was no longer formidable. Three years after his defeat at Beresteczko, Chmielnicki, finding himself unable to cope with the Poles single-handed, very reluctantly transferred his allegiance to the tsar, and the same year the tsar's armies invaded Poland, still bleeding from all but mortal wounds inflicted on her by the Cossacks. The war thus begun, and known in Russian history as the Thirty Years' War, far exceeded even the Thirty Years' War in grossness and brutality. It resembled nothing so much as a hideous scramble of ravening beasts and obscene fowls for the dismembered limbs of a headless carcass, for such did Poland seem to all the world before the war was half over. In the summer of 1655, moreover, while the Republic was still reeling beneath the shock of the Muscovite invasion, Charles X. of Sweden, on the flimsiest of pretexts, forced a war upon reluctant and inoffensive Poland, simply to gratify his greed of martial glory, and before the year was out his forces had occupied the capital, the coronation city and the best half of the land. King John Casimir, betrayed and abandoned by his own subjects, fled to Silesia, and profiting by the cataclysm which, for the moment, had swept the Polish state out of existence, the Muscovites, unopposed, quickly appropriated nearly everything which was not already occupied by the Swedes. At this crisis Poland owed her salvation to two events—the formation of a general league against Sweden, brought about by the appre- hensive court of Vienna and an almost simultaneous popular outburst of religious enthusiasm on the part of the Polish people. The first of these events, to be dated from the alliance between the emperor Leopold and John Casimir, on the 27th of May 1657, led to a truce with the tsar and the welcome diversion of all the Muscovite forces against Swedish Livonia. The second event, which with the heroic and successful defence of the monastery of Czestochowa by Prior Kordecki against the Swedes, resulted in the return of the Polish king from exile, the formation of a national army under Stephen Czarniecki and the recovery of almost all the lost provinces from the Swedes, who were driven back headlong to the sea, where with difficulty they held their own. On the sudden death of Charles X. (Feb. 13, 1660), Poland gladly seized the opportunity of adjusting all her outstanding differences with Sweden. By the peace of Oliva (May 3, 1660), made under French mediation, John Casimir ceded Livonia, and renounced all claim to the Swedish crown. The war with Muscovy was then prosecuted with renewed energy and extraordinary success. In the autumn of 1661 the Russian commanders were routed at Zeromsk, and nearly all the eastern provinces were recovered. In 1665 a greater triumph was secured; in the battle of Parnawa, which the Poles fought on their own soil, Poland seemed most brilliant; but at the very moment when she needed all her armed strength to sustain her diplomacy, the rebellion of one of her leading magnates, Prince Lubomirsky, involved her in a dangerous civil war, compelled her to reopen negotiations with the Muscovites, at Andrusov, under far more unfavourable conditions, and after protracted negotiations practically to accept the Muscovite terms. By the truce of Andrusowo (Feb. 11, 1667) Poland received back the Truce from Muscovy Vitebsk, Polotsk and Polish Livonia, of Andrus- but ceded in perpetuity Smolensk, Sycyvers, Cher. of Andrusowo 1665, remaining to Muscovy and the whole of the eastern bank of the Dnieper, including the towns of Konotop, Pereyaslav, and the provinces of Zhytomyr and Izyum. The Cossacks of the Dnieper were henceforth to be under the joint domination of the tsar and the king of Poland. Kiev, the religious metropolis of western Russia, was to remain in the hands of Muscovy for two years. The "truce" of Andrusov proved to be one of the most permanent peace of history, and Kiev, though only pledged for two years, was never again to be separated from the Orthodox Slavonic state to which it rightly belonged. But for the terrible and persistent ill-luck of Poland it is doubtful whether the "truce" of Andrusovo would ever have been signed. The truce which it concluded was to be the last open struggle between the two great powers, for Muscovy under its new ruler, Peter the Great, over Poland was steadily to increase, without any struggle at all, the Republic being already stricken with that creeping paralysis which ultimately left her a prey to her neighbours. Muscovy
had done with Poland as an adversary, and had no longer any reason to fear her ancient enemy.

Poland had, in fact, emerged from the cataclysm of 1568–1667 a moribund state, though her not unskifful diplomacy had enabled her for a time to save appearances. Her territorial losses, though considerable, were, in the circumstances, not excessive, and she was still a considerable power in the opinion of Europe. But a fatal change had come over the country during the age of the Vasas. We have already seen how the ambition of the oligarchs and the lawlessness of the szlachta had reduced the executive to impotence, and rendered anything like rational government impossible. But these demoralizing and disintegrating influences had been suspended by the religious revival due to the Catholic reaction and the Jesuit propaganda, a revival which reached its height towards the end of the 16th century. This, on the whole, salutary and edifying movement permeated public life, and produced a series of great captains who cheerfully sacrificed themselves for their country, and would have been saints if they had not been heroes. But this extraordinary religious revival had wellnigh spent itself by the middle of the 17th century. Its last manifestation was the successful defence of the monastery of Czestochowa by Prior Kordecki against the finest troops in Europe, its last representative was Stephen Czarniecki, who brought the fugitive John Casimir back from exile and reinstated him on his tottering throne. The succeeding age was an age of unmitigated egotism, in which the old ideals were abandoned and the old examples were forgotten. It synchronized with, and was partly determined by, the new political system which was spreading all over Europe, the system of dynastic diplomatic competition and the unscrupulous employment of unlimited secret service funds. This system, which dates from Richelieu and culminated in the reign of Louis XIV., was based on the secular rivalry of the houses of Bourbon and Habsburg, and presently divided all Europe into two hostile camps. Louis XIV. is said to have expended 50,000,000 livres a year for bribing purposes, the court of Vienna was scarcely less liberal, and very soon nearly all the monarchs of the Continent and their ministers were in the pay of one or other of the antagonists. Poland was no exception to the general rule. Her magnates, having already got all they could out of their own country, looked eagerly abroad for fresh El Dorados. Before long most of them had become the hirings of France or Austria, and the value demanded for their wages was, not infrequently, the betrayal of their own country. To do them justice, the szlachta at first were not only free from the taint of official corruption, but endeavoured to fight against it. Thus, at the election of 1669, one of the deputies, Pieniaszek, moved that a new and higher form of education be introduced to educate the deputies of the general confederation, to the effect that every senator and deputy should solemnly swear not to take bribes, while another szlacz proposed that the ambassadors of foreign Powers should be excluded permanently from the Polish elective assemblies. But the flighty and ignorant szlachta not only were incapable of any sustained political action, but they themselves unconsciously played into the hands of the enemies of their country by making the so-called liberum veto an integral part of the Polish constitution. The liberum veto was based on the assumption of the absolute political equality of every Polish gentleman, with the inevitable corollary that every measure introduced into the Polish diet must be adopted unanimously. Consequently, if any single deputy believed that a measure already approved of by the rest of the house might be injurious to his constituency, he had the right to rise and exclaim nie poniewaz, “I disapprove,” when the measure in question fell at once to the ground. Subsequently this vicious principle was extended still further. A deputy, by interposing his individual veto, could at any time dissolve the diet, when all measures previously passed had to be re-submitted to the consideration of the following diet. The liberum veto seems to have been originally devised to cut short interminable debates in times of acute crisis, but it was generally used either by highly placed criminals, anxious to avoid an inquiry into their misdeeds,1 or by malcontents, desirous of embarrassing the executive. The origin of the liberum veto is obscure, but it was first employed by the deputy Wladislaus Siciński, who dissolved the diet of 1652 by means of it, and before the end of the 17th century it was used so frequently and recklessly that all business was frequently brought to a standstill. In later days it became the chief instrument of foreign ambassadors for dissolving inconvenient diets, as a deputy could always be bribed to exercise his veto for a handsome consideration.

The Polish crown first became an object of universal competition in 1573, when Henry of Valois was elected. In 1575, and again in 1597, it was put up for public auction when the Grand Batory and the Swede Sigismund respectively gained the prize. But at all three elections, though money and intrigue were freely employed, they were not the determining factors of the contest. The Polish gentry were still the uffires as well as the stake-holders; the best candidates generally won the day; and the defeated competitors were driven out of the country by force of arms if they did not take their discomfiture, after a fair fight, like sportsmen. But with the election of Michael Wiśniowiecki in 1669 a new era began. In this case a native Pole was freely elected by the unanimous vote of his countrymen. Yet a few weeks later the Poles were placed in a whole series of conspiracies for the purpose of dethroning his lawful sovereign, and openly placed himself beneath the protection of Louis XIV. of France, just as the rebels of the 18th century placed themselves under the protection of Catherine II. of Russia. And this rebel was none other than John Sobieski, at a later day the heroic deliverer of Vienna! If heroes could so debase themselves, can we wonder if men who were not heroes lent themselves to every sort of villainy? We have come, in fact, to the age of utter shamelessness, when disappointed place-hunters openly invoked foreign aid against their own country. Sobieski himself, as John III. (he succeeded Michael in 1674), was badly paid the penalty of his past lawlessness, to the uttermost farthing. Despite his brilliant military achievements (see John III., KING OF POLAND), his reign of twenty-two years was a failure. His victories over the Turks were fruitless so far as Poland was concerned. His belated attempts to reform the constitution only led to conspiracies against his life and crown, in which the French faction, which he had been the first to encourage, took an active part. In his later years Lithuania was in a state of chronic revolt, while Poland was bankrupt both morally and materially. He died a broken-hearted man, prophesying the inevitable ruin of a nation which he himself had done so much to demoralize. It was left for Poland to sink lower than she had sunk already. Yet an era was now to follow, compared with which even the age of Sobieski seemed to be an age of gold. This was the Saxon period which, with occasional violent interruptions, was to drag on for nearly seventy years. By the time it was over Poland was irretrievably doomed. It only remained to be seen how that doom would be accomplished.

On the death of John III. no fewer than eighteen candidates for the vacant Polish throne presented themselves. Austria supported James Sobieski, the eldest son of the late king, France Francis Louis Prince of Conti (1663–1697). But the successful competitor was Frederick Augustus, elector of Saxony, who cheerfully renounced Lutheranism for the coveted crown, and won the day because he happened to arrive last of all, with fresh funds, when the agents of his rivals had spent all their money. He was crowned, as Augustus II., on the 15th of September 1697, and his first act was to expel from the country the prince of Conti, the elect of a respectable minority, directed by the cardinal primate Michał Radziejowski (1645–1705), whom Augustus II. subsequently bought over for 75,000 thalers.

1. Thus the Sapiehas, who had been living on rapine for years, dissolved the diet of 1668 by means of the veto of one of their hirings, for fear of an investigation into their conduct.
Good luck attended the opening years of the new reign. In 1690 the long Turkish War, which had been going on ever since 1683, was concluded by the peace of Karlowitz, whereby Podolia, the Ukraine and the fortress of Kamienks Podolski were retroceded to the Republic by the Ottoman Porte. Immediately afterwards Augustus was persuaded by the plausible Livonian exile, Johan Reinhold Patkul, to form a nefarious league with Frederick of Denmark and Peter of Russia, for the purpose of despoiling the youthful king of Sweden, Charles XII. (see Sweden: History). This he did as elector of Saxony, but it was the unfortunate Polish republic which paid for the hazardous speculation of its newly elected king. Throughout the Great Northern War (see Sweden: History), warfare and intrigue were rife among a rabble of nations, for within a period of twenty years (1700–1720), all the belligerents treated Poland as if she had no political existence. Swedes, Saxons and Russians not only lived upon the country, but plundered it systematically. The diet was the humble servant of the conqueror of the moment, and the leading magnates chose their own sides without the slightest regard for the interests of their country, the Lithuanians for the most part supporting Charles XII, while the Poles divided their allegiance between Augustus and Stanislaus Leszczyński, whom Charles placed upon the throne in 1704 and kept there till 1709. At the end of the war Poland was ruined materially as well as politically. Augustus attempted to indemnify himself for his failure to obtain Livonia, his covenanted share of the Swedish plunder, by offering Frederick William of Prussia Courland, Polish Prussia and even part of Great Poland, provided that he were allowed a free hand in the disposal of the rest of the country. When Prussia declined this tempting offer for fear of Russia, Augustus went a step farther and actually suggested that "the four eagles" should divide the banquet between them. He died, however (Feb. 1, 1733) before he could give effect to this shameless design.

On the death of Augustus II, Stanislaus Leszczyński, who had, in the meantime, become the father-in-law of Louis XV., attempted to regain his throne with the aid of a small French army corps and 4,000,000 livres from Versailles. Some of the best men in Poland, including the Czartoryskys, were also in his favour, and on the 26th of August 1733 he was elected king for the second time. But there were many malcontents, principally among the Lithuanians, who solicited the intervention of Russia in favour of the elector of Saxony, son of the late king, and in October 1733 a Russian army appeared before Warsaw and compelled a phantom diet (it consisted of but 15 senators and 500 of the szlachta) to proclaim Augustus III. From the end of 1733 till the 30th of June 1734 Stanislaus and his partisans were besieged by the Russians in Danzig, their last refuge, and with the surrender of that fortress the cause of Stanislaus was lost. He retired once more to his little court in Lorraine, with the title of king, leaving Augustus III. in possession of the kingdom.

Augustus III. was disqualified by constitutional indolence from taking any active part in affairs. He left everything to his omnipotent minister, Count Heinrich Brühl, and Brühl entrusted the government of Poland to the Czartoryskys, who had intimate relations of long standing with the court of Dresden.

The Czartoryskys, who were to dominate Polish politics for the next half-century, came of an ancient Ruthenian stock which had intermarried with the Jagiellons at an early date, and had always been remarkable for their civic virtues and political sagacity. They had powerfully contributed to the adoption of the Union of Lublin; were subsequently received into the Roman Catholic Church; and dated the beginning of their influence in Poland proper from the time (1674) when Florian Czartoryski became primate there. Florian's nephews, Fryderyk, Michal and Augustus, were now the principal representatives of "the Family," as their opponents sarcastically called them. The former, through the influence of Augustus's minister and favourite Brühl, had become, in his twenty-eighth year, vice-chancellor and subsequently grand chancellor of Lithuania, was always the political head of the family. His brother and Augustus, after fighting with great distinction against the Turks both by land and sea (Prince Eugene decorated him with a sword of honour for his valour at the siege of Belgrade), had returned home to marry Sophia Sieniawska, whose fabulous dowry won for her husband the sobriquet of "the Family Croesus." Their sister Constancia had already married Stanislaus Poniatowski, the father of the future king. Thus wealth, position, court influence and ability combined gave the Czartoryskys a commanding position in Poland, and, to their honour be it said, they had determined from the first to save the Republic, whose impending ruin in existing circumstances they clearly foresaw, from a new political and constitutional reconstruction which would include the abolition of the liberum veto and the formation of a standing army.

Unfortunately the other great families of Poland were obstinately opposed to any reform or, as they called it, any "violation" of the existing constitution. The Potoccy, whose possessions in south Poland and the Ukraine covered thousands of square miles, the Radziwillowie, who were omnipotent in Lithuania and included half a dozen millionaires amongst them, the Labomirscys and their fellows, hated the Czartoryskys because they were too eminent, and successfully obstructed all their well-meant efforts. The castles of these great lords were the foci of the social and political life of their respective provinces. Here they lived like little princes, surrounded by thousands of retainers, whom they kept for show alone, making no attempt to organize and discipline this excellent military material for the defence of their defenceless country. Here congregated hundreds of the younger szlachta, fresh from their school benches, whence they brought nothing but a smattering of Latin and a determination to make their way by absolute subservience to their "elder brethren," the poniński. These were the men who, a little later, at the bidding of their benefactors, dissolved one inconvenient diet after another; for it is a significant fact that during the reign of the two Augustuses every diet was dissolved in this way by the hirings of some great lord or, still worse, of some foreign potentate. In a word constitutional government had practically ceased, and Poland had become an arena in which contesting clans strove together for the mastery.

It was against this primitive state of things that the Czartoryskys struggled, and struggled in vain. First they attempted to abolish the liberum veto with the assistance of the Saxon court where they were supreme, but fear of foreign complications and the opposition of the Potoccy prevented anything being done. Then they broke with their old friend Brühl and turned to Russia. Their chief intermediary was their nephew Stanislaus Poniatowski, whom they sent, as Saxon minister, to the Russian court in the suite of the English minister Hanbury Williams, in 1755. The handsome and insinuating Poniatowski speedily won the susceptible heart of the grand-duchess Catherine, but he won nothing else and returned to Poland in 1759 somewhat discredited. Disappointed in their hopes of Russia, the Czartoryskys next attempted to form a confederation for the deposition of Augustus III., but while the strife of factions was still at its height the absentee monarch put an end to the struggle by expiring, conveniently, on the 5th of October 1763.

The interregnum occurring on the death of Augustus III. befell at a time when all the European powers, exhausted by the Seven Years' War, earnestly desired peace. The position of Poland was, consequently, much more advantageous than it had been on every other similar occasion, and if only the contending factions had been able to agree and unite, the final catastrophe might, perhaps, even now, have been averted. The Czartoryskys, of all men, were bound by their principles and professions to set their fellow citizens an example of fraternal concord. Yet they rejected with scorn and derision the pacific overtures of their political opponents, the Potoccy, the Radziwillowie, and the Branisçys, Prince Michael openly declaring that of the two tyrannies he preferred the tyranny of the Muscovite to the

1 The fourth eagle was the White Eagle, i.e. Poland.

2 Michal Kazimierz Radziwiłł alone was worth thirty millions.
tyranny of his equals. He had in fact already summoned a Russian army corps to assist him to reform his country, which some of his own subjects misinterpreted as a threat to the liberties and the unsworn complacency of the rival magnates.

The simplicity of the Czartoryscy was even more mischievous than their haughtiness. When the most enlightened statesmen of the Republic could seriously believe in the benevolent intentions of Russia the end was not far off. Their naïve expectations were very speedily disappointed. Catherine II. and Frederick II. had already determined (Treaty of St Petersburg, April 22, 1764) that the existing state of things in Poland must be maintained, and as early as the 18th of October 1765 Catherine had recommended the election of Stanislaus Poniatowski as "the individual most convenient for our common interests." The personal question did not interest Frederick: so long as Poland was kept in an anarchical condition he cared not who was called king. Moreover, the opponents of the Czartoryscy made no serious attempt to oppose the entry of the Russian troops. At least 40,000 men were necessary for the purpose, and these could have been obtained for 200,000 ducats; but a congress of magnates, whose collective fortunes amounted to hundreds of millions, having decided that it was impossible to raise this sum, there was nothing for it but to fight a few skirmishes and then take refuge abroad. The Czartoryscy now fancied themselves the masters of the situation. They at once proceeded to pass through the convocation diet a whole series of salutary measures. Four special commissions were appointed to superintend the administration of justice, the police and the finances. The extravagant powers of the grand hetmans and the grand marshals were reduced. All financial and economical questions before the diet were henceforth to be decided by a majority of votes. Shortly afterwards Stanislaus Poniatowski was elected king (Sept. 7, 1764) and crowned (Nov. 25). But at the beginning of 1766 Prince Nicholas Repnin was sent as Russian minister to Warsaw with instructions which can only be described as a carefully elaborated plan for destroying the Republic. The first weapon employed was the dissident question. At that time the population of Poland was, in round numbers, 11,500,000, of whom about 1,000,000 were dissidents or dissenters. Half of these were the Protestants of the towns of Polish Prussia and Great Poland, the other half was composed of the Orthodox population of Lithuania. The dissidents had no political rights, and their religious liberties had also been unjustly restricted; but two-thirds of them being agricultural labourers, and most of the rest artisans or petty tradesmen, they had no desire to enter public life, and were so ignorant and illiterate that their new protectors, on a closer acquaintance, became heartily ashamed of them. Yet it was for these persons that Repnin, in the name of the empress, now demanded absolute equality, political and religious, with the gentlemen of Poland. He was well aware that an aristocratic and Catholic assembly like the sejm would never concede so preposterous a demand. He also calculated that the demand itself would make the szlachta suspicious of all reform, including the Czartoryscy reforms, especially as both the king and his uncles were generally unpopular, as being innovators under foreign influence. His calculations were correct. The sejm of 1766 not only rejected the dissident bill, but repealed all the Czartoryscy reforms and insisted on the retention of the liberum veto as the foundation of the national liberties. The discredit into which Stanislaus had now fallen encouraged the Saxon party, led by Gabriel Podolski (1759-1777), to form a combination for the purpose of driving Poniatowski out. The combined efforts would never consent to such a measure; but he secretly encouraged the plot for his own purposes, with signal success. Early in 1767 the malcontents, fortified by the adhesion of the leading Catherine II., political refugees, formed a confederation at Radom, whose first act was to send a deputation to St Petersburg, petitioning Catherine to guarantee the liberties of the Republic, and allow the form of the Polish constitution to be settled by the Russian ambassador at Warsaw. With this carte blanche in his pocket, Repnin proceeded to treat the diet as if it were already the slave of the Russian emperor. But despite threats, wholesale corruption and the presence of Russian troops outside and even inside the izba, or chamber of deputies, the patriots, headed by four bishops, Włodzimierz Hieronim Sierakowski (1699-1784) of Lemberg, Feliks Pawel Turski of Chelm (1729-1800), Kajetan Ignacy Soltyk of Cracow (1715-1788), and Józef Jendrzei Zaluski of Kiev (1702-1774), offered a determined resistance to Repnin's demands. Only when brute force in its extremest form had been ruthlessly employed, only when three senators and some deputies had been arrested in full session by Russian grenadiers and sent as prisoners to Kaluga, did the opposition collapse. The liberum veto and all the other ancient abuses were now declared unalterable parts of the Polish constitution, which was placed under the guarantee of Russia. All the edicts against the dissidents were, at the same time, repealed.

This shameful surrender led to a Catholic patriotic uprising, known as the Confederation of Bar, which was formed on the 20th of February 1768, at Bar in the Ukraine, by a handful of small squires. It never had a chance of permanent success, though, feebly fed by French subsidies and French volunteers, it lingered on for four years, till finally suppressed in 1772. But, insignificant itself, it was the cause of great events. Some of the Bar confederates, scattered by the Russian regulars, fled over the Turkish border, pursued by their victors. The Turks, already alarmed at the progress of the Russians in Poland, formed a league, at that time French ambassador at Constantinople, at once declared war against Russia. Seriously disturbed at the prospect of Russian aggrandizement, the idea occurred, almost simultaneously, to the courts of Berlin and Vienna that the best mode of preserving the equilibrium of Europe was for all three powers to readjust their territories at the expense of Poland. The idea of a partition of Poland was nothing new, but the vastness of the country, and the absence of sufficiently powerful and united enemies, had hitherto saved the Republic from spoliation. But now that Poland lay utterly helpless and surrounded by the three great military monarchies of Europe, nothing could save her. In February 1769 Frederick sent Count Rochus Friedrich Lynar (1708-1783) to St Petersburg to sound the empress as to the expediency of a partition, in August Joseph II. solicited an interview with Frederick, and in the course of the summer the two monarchs met, first at Neisse in Silesia and again at Neustadt in Moravia. Nothing definite as to Poland seems to have been arranged, but Prince Kaunitz, the Austrian chancellor, was now encouraged to take the first step by occupying, in 1770, the county of Zips, which had been hypothecated by Hungary to Poland in 1442 and never redeemed. This act decided the other confederates. In June 1770 Frederick surrounded those of the Polish provinces he coveted with a military cordon, ostensibly to keep out the cattle plague. Catherine's confidence had been previously obtained by a special mission of Prince Henry of Prussia to the Russian capital. The first treaty of partition was signed at St Petersburg between Prussia and Russia on the 6-17th of February 1772; the second treaty, which admitted Austria also to a share of the spoil, on the 5-16th of August the same year. It is unnecessary to recapitulate the unheard-of atrocities by which the consent of the sejm to this act of brigandage was at last extorted (Aug. 18, 1773). Russia obtained the palatines of Vitebsk, Polotsk Mscislaw: 1586 sq. m. of territory, with a population of 550,000 and an annual revenue of 1,050,000 guldens. Austria got the greater part of Galicia, minus Cracow: 1710 sq. m., with a population of 865,000 and an annual revenue of 1,050,000 guldens. Prussia received the maritime palatinate minus Danzig, the palatinates of Kulm minus Thorn, Great Poland as far as the Nizta, and the palatinates of Marienburg and Ermeland: 629 sq. m., with a population of 378,000, and an annual revenue of 534,000 thalers. In fine, Poland lost about one-fifth of her population and one-fourth of her territory.
In return for these enormous concessions the partitioning powers presented the Poles with a constitution superior to anything they had ever been able to devise for themselves. The most mischievous of the ancient abuses, the elective monarchy and the liberum veto, were of course retained. Poland was to be dependent on her despots, but they evidently meant to make her a serviceable dependant. The government was henceforth to be in the hands of a rada niestojaca, or permanent council of thirty-six members, eighteen senators and eighteen deputies, elected biennially by the sejm in secret ballot, subdivided into the five departments of foreign affairs, police, war, justice and the exchequer, whose principal members and assistants, as well as all other public functionaries, were to have fixed salaries. The royal prerogative was still further reduced. The king was indeed the president of the permanent council, but he could not summon the diet without its consent, and in all cases of preferment was bound to select one out of three of the council's nominees. The annual budget was fixed at 30,000,000 Polish gulden, out of which a regular army of 30,000 men was to be maintained. Sentiment apart, the constitution of 1773 was of distinct benefit to Poland. It made for internal stability, order and economy, and enabled her to develop and husband her resources, and devote herself uninterruptedly to the new burning question of national education. For the shock of the first partition was so far salutary that it awoke the public conscience to a sense of the national inferiority; stimulated the younger generation to extraordinary patriotic efforts; and thus went far to produce the native reformers who were to do such wonders during the great quadrennial diet.

It was the second Turkish War of Catherine II. which gave patriotic Poland her last opportunity of re-establishing her independence. The death of Frederick the Great (Aug. 17, 1786) completely deranged the balance of power in Europe. The long-standing accord between Prussia and Russia came to an end, and while the latter drew nearer to Austria, the former began to look to the Western powers. In August 1787 Russia and Austria provoked the Porte to declare war against them both, and two months later a defensive alliance was concluded between Prussia, England and Holland, as a counterpoise to the alarming preponderance of Russia. In June 1788 Gustavus III. of Sweden also attacked Russia, with 50,000 men, while in the south the Turks held the Muscovites at bay beneath the walls of Ochakov, and drove back the Austrian invaders into Transylvania. Prussia, emboldened by Russia's difficulties, now went so far as to invite Poland also to forsake the Russian alliance, and placed an army in the field to assist the Porte. Under these exceptional circumstances that the "four years' diet" assembled (Oct. 6, 1788). Its leaders, Stanislaw Malachowski, Hugo Kollontaj and Ignaty Potocki, were men of character and capacity, and its measures were correspondingly vigorous. Within a few months of its assembling it had abolished the permanent council; enlarged the royal prerogative; raised the army to 65,000 men; established direct communications with the Western powers; rejected an alliance which Russia, alarmed at the rapid progress of events, had hastened to offer; declared its own session permanent; and finally settled down to the crucial task of reforming the constitution on modern lines. But the difficulties the Patriots were commensurate with their energies, and though the new constitution was drafted so early as December 1789, it was not till May 1791 that it could safely be presented to the diet. Meanwhile Poland endeavoured to strengthen her position by an advantageous alliance with Prussia. Frederick William II. stipulated, at first, that Poland should surrender Danzig and Thorn, and Pitt himself endeavoured to persuade the Polish minister Michal Kleophas Ogiński (1765-1833) that the protection of Prussia was worth the sacrifice. But the Poles proving obstinate, and Austria simultaneously displaying a disquieting interest in the welfare of the Republic, Prussia, on the 20th of March 1791, concluded an alliance with Poland which engaged the two powers to guarantee each other's possessions and render mutual assistance in case either were attacked.

But external aid was useless so long as Poland was hampered by her anarchical constitution. Hitherto the proceedings of the diet had not been encouraging. The most indispensable reforms had been frantically opposed, the debate on the reorganization of the army had alone lasted six months. It was only by an audacious surprise that Kollontaj and his associates contrived to carry through the new constitution. Taking advantage of the Easter recess, when most of the malcontents were out of town, they suddenly, on the 3rd of May, brought the whole question before the diet and demanded urgency for it. Before the opposition could protest, the marshal of the diet produced the latest foreign despatches, which unanimously predicted another partition, whereupon, at the solemn adjuration of Ignaty Potocki, King Stanislaus exhorted the deputies to accept the new constitution as the last means of saving their country, and himself set the example by swearing to defend it.

The revolution of the 3rd of May 1792 converted Poland into a mixed duchy, single limited monarchy, with ministerial responsibility and duenial parliaments. The Liberum veto and all the intricate and obstructive machinery of the anomalous old system were for ever abolished. All invidious class distinctions were done away with. The franchise was extended to the towns. Serfdom was mitigated, preparatory to its entire abolition; absolute religious toleration was established, and every citizen declared equal before the law. Frederick William II. officially congratulated Stanislaus on the success of "the happy revolution which has at last given Poland a wise and regular government," and declared it should henceforth be his "chief care to maintain and confirm the ties which unite us." Colonel, the Austrian minister at St Petersburg, writing to his court immediately after the reception of the tidings at the Russian capital, describes the empress as full of consternation at the idea that Poland under an hereditary dynasty might once more become a considerable power. But Catherine, still in difficulties, was obliged to watch in silence the collapse of her party in Poland, and submit to the double humiliation of recalling her ambassador and withdrawing her army from the country. Even when the peace of Jassy (Jan. 9, 1792) finally freed her from the Turk, she waited patiently for the Polish malcontents to afford her a pretext and an opportunity for direct and decisive interference. She had not long to wait. The revolution of the 30th of May had once been signed when Felix Potocki, Sergey Razevski and Tadeusz Branicki, three of the chief dignitaries of Poland, hastened to St Petersburg, and there entered into a secret convention with the empress, whereby she undertook to restore the old constitution by force of arms, but at the same time promised to respect the territorial integrity of the Republic. On the 14th of May 1792 the conspirators formed a confederation, consisting, in the first instance, of only ten other persons, at the little town of Targowica in the Ukraine, protesting against the constitution of the 3rd of May as tyrannical and revolutionary, and at the same time the new Russian minister at Warsaw presented a formal declaration of war to the king and the diet. The diet had been dissolved before. The army was at once dispatched to the frontier; the male population was called to arms, and Ignaty Potocki was sent to Berlin to claim the assistance stipulated by the treaty of the 10th of March 1791. The king of Prussia, in direct violation of all his oaths and promises, declined to defend a constitution which had never had his "concurrence." Thus Poland was left entirely to her own resources. The little Polish army of 46,000 men, under Prince Joseph Poniatowski and Tadeusz Kościusko, did all that was possible under the circumstances. For more than three months they kept back the invaders, and, after winning three pitched battles, retired in perfect order on the capital (see PONIATOWSKI, and

1 At the very next diet, 1776, the Poles themselves reduced the army to 18,000 men.

2 On the death of Stanislaus, the crown was to pass to the family of the elector of Saxony.
KOŚCIUSZKO. But the king, and even Kollontaj, despairing of success, now acceded to the confederation; hostilities were suspended; the indignant officers threw up their commissions; the revolutionary distresses all but lasted to the close. The reformers fled abroad; and the constitution of the 3rd of May was abolished by the Targowianists as "a dangerous novelty."

The Russians then poured into eastern Poland; the Prussians, at the beginning of 1793, alarmed lest Catherine should appropriate the whole Republic, occupied Great Poland; and a diminutive, debased and helpless assembly met at Grodno in order, in the midst of a Russian army corps, "to come to an amicable understanding" with the partitioning powers. After every conceivable means of intimidation had been unscrupulously applied for twelve weeks, the second treaty of partition was signed at three o'clock on the morning of the 23rd of September 1793. By this *pactum subjectionis*, as the Polish patriots called it, Russia got all the eastern provinces of Poland, extending from Livonia to Moldavia, comprising a quarter of a million of square miles, while Prussia got Drohyn, Kuyavia and the greater part of Great Poland, with Thorn and Danzig. Poland was now reduced to one-third of her original dimensions, with a population of about three and a half millions.

The focus of Polish nationality was now transferred from Warsaw, where the Targowianists and their Russian patrons reigned supreme, to Leipzig, whither the Polish patriots, Kościuszko, Kollontaj and Ignacy Potocki, among the number, assembled from 12 provinces. From the first they meditated a national rising, but their ignorance, enthusiasm and simplicity led them to commit blunder after blunder. The first of such blunders was Kościuszko's mission to Paris, in January 1794. He was full of the idea of a league of republics against the league of sovereigns; but he was unaware that the Jacobins themselves were already considering the best mode of detaching Prussia, Poland's worst enemy, from the anti-French coalition. With a hypocrisy worthy of the diplomacy of "the tyrants," the committee of public safety declared that it could not support an insurrection engineered by aristocrats, and Kościuszko returned to Leipzig empty-handed. The next blunder of the Polish refugees was to allow themselves to be drawn into a premature rising by certain Polish officers in Poland who, to prevent the incorporation of their regiments in the Russian army, openly revolted and led their troops from Warsaw to Cracow. Kościuszko himself condemned their rashness; but, when the Russian troops began to concentrate, his feelings grew too strong for him, and early in April he himself appeared at Cracow. In an instant the mutiny became a revolution. The details of the heroic but useless struggle will be found elsewhere (see Kościuszko, Kollontaj, Potocki, Ignaty, Dombrowski). Throughout April the Polish arms were almost universally successful. The Russians were defeated in more than one pitched battle; three-quarters of the ancient territory was recovered, and Warsaw and Vilna, the capitals of Poland and Lithuania respectively, were liberated. Kościuszko was appointed dictator, and a supreme council was established to assist him. The first serious reverse, at Szczekociny (June 5), was more than made up for by the successful defence of Warsaw against the Russians and Prussians (July 9 to Sept. 6); but in the meantime the inextenable lawlessness of the Poles had asserted itself, as usual, and violent and ceaseless dissensions, both in the supreme council and in the army, neutralized the superhuman efforts of the unfortunate but still undaunted dictator. The death-blow to the movement was the disaster of Maciejowice (Oct. 19), and it expired amidst the carnage of Praga (Oct. 29), though the last Polish army corps did not capitulate till the 18th of November. Yet all the glory of the bitter struggle was with the vanquished, and if the Poles, to the last, had shown themselves children in the science of government, they had at least died on the field of battle like men. The greed of the three partitioning powers very nearly led to a rupture between Austria and Prussia; but the tact and statesmanship of the empress of Russia finally adjusted all difficulties. On the 24th of October 1795 Prussia acceded to the Austro-Russian partition compact of the 3rd of January, and the distribution of the conquered provinces was finally regulated on the 10th of October 1796. By the third treaty of partition Austria had to content with Western Galicia and Southern Masovia; Prussia took Podlachia, and the rest of Masovia, with Warsaw; and Russia all the rest.

The immediate result of the third partition was an immense emigration of the high-spirited Poles who, during the next ten years, fought the battles of the French Republic and of Napoleon all over Europe, but principally against their own enemies, the partitioning powers. They were known as the Polish legionaries, and were commanded by the best Polish generals, e.g. Joseph Poniatowski and Dombrowski. Only Kościuszko stood aloof. Even when, after the peace of Tilsit, the independent grand-duchy of Warsaw was constructed out of the central provinces of Prussian Poland, his distrust of Napoleon proved to be invincible. He was amply justified by the course of events. Napoleon's anxiety to conciliate Russia effectually prevented him from making Poland large and strong enough to be self-supporting. The grand-duchy of Warsaw originally consisted of about 1850 sq. m., to which Western Galicia and Cracow, about 900 sq. m. more, were added in 1809. The grand-duchy was, from first to last, a mere recruiting-ground for the French emperor. Its army was limited, on paper, to 30,000 men; but in January 1812 65,000, and in November of the same year 75,000 recruits were drawn from it. The constitution of the little state was dictated by Napoleon, and, subject to the exigencies of war, was on the French model. Equality before the law, absolute religious toleration and local autonomy, were its salient features. The king of Saxony, as grand-duke, took the initiative in all legislative matters; but the administration was practically controlled by the French.

(R.N.B.)

The Congress Kingdom, 1813-1863—The Grand Duchy of Warsaw perished with the Grand Army in the retreat from Moscow in 1812. The Polish troops had taken a prominent part in the invasion of Russia, and their share in the plundering of Smolensk and of Moscow had intensified the racial hatred felt for them by the Russians. Those of them who survived or escaped the disasters of the retreat fled before the tsar's army and followed the fortunes of Napoleon in 1813 and 1814. The Russians occupied Warsaw on the 18th of February 1813 and overran the grand duchy, which thus came into their possession by conquest. Some of the Poles continued to hope that Alexander would remember his old friend and Poland, and would restore their kingdom under his own rule. Nor was the tsar unwilling to encourage their delusion. He himself cherished the desire to re-establish the kingdom for his own advantage. As early as the 13th of January 1813 he wrote to assure his former favourite and confidant, Prince Adam Czartoryski, that, "Whatever the Poles do now to aid in my success, will at the same time serve to forward the realization of their hopes." But the schemes of Alexander could be carried out only with the co-operation of other powers. They refused to consent to the annexation of Saxony by Prussia, and other territorial arrangements which would have enabled him to unite all Poland in his own hand. By the final act of the Congress of Vienna, signed on the 9th of June 1815, Poland was divided between Prussia, Austria and Russia, with one trifling exception: Cracow with its population of 60,000 was erected into a republic embedded in Galicia. Posen and Gnesen, with a population of 850,000, were left to Prussia. Austria remained in possession of Galicia with its 1,500,000 inhabitants. Lithuania and the Ruthenian Palatinate, the spoil of former partitions, continued to be incorporated with Russia. The remnant was constituted as the so-called Congress Kingdom under the emperor of Russia as king (tsar) of Poland. It had been stipulated by the Final Act that the Poles under foreign rule should be endowed with institutions to preserve their national existence.
according to such forms of political existence as the governments to which they belonged shall think fit to allow them.

Alexander, who had a sentimental regard for freedom, so long as it was obedient to himself, had promised the Poles a constitution in April 1815 in a letter to Ostroumow, the president of the senate at Warsaw. His promise was publicly proclaimed on the 25th of May, and was reaffirmed in the Zamok or palace at Warsaw and the cathedral of St John on the 20th of June. The constitution thus promised was duly drafted, and was signed on the 30th of November. It contained 165 articles divided under seven heads. The kingdom of Poland was declared to be united to Russia, in the person of the tsar, as a separate political entity. The kingdom was the Congress Kingdom, for the vague promises of an extension to the east which Alexander had made to the Poles were never fulfilled. Lithuania and the Ruthenian Palatinates continued to be incorporated with Russia as the Western Provinces and were divided from the Congress Kingdom by a customs barrier till the reign of Nicholas I. The kingdom of Poland thus defined was to have at its head a lieutenant of the emperor (namiestnik), who must be a member of the Imperial house or a Pole. The first holder of the office, General Zajoncze (1752-1826), was a veteran who had served Napoleon. Roman Catholicism was recognized as the religion of the state, but other religions were tolerated. Liberty of the Press was promised subject to the passing of a law to restrain its abuses. Individual liberty, the use of the Polish language in the law courts, and the exclusive employment of Poles in the civil government were secured by the constitution. The machinery of government was framed of a council of state, at which the Imperial government was represented by a commissioner plenipotentiary, and a diet divided into a senate composed of the princes of the blood, the patines and councillors named for life, and a house of nuntii elected for seven years, 77 chosen by the "dietines" of the nobles, and 51 by the commons. The diet was to meet every other year for a session of thirty days, and was to be renewed by thirds every two years. Poland retained its flag, and a national army based on that which had been raised by and had fought for Napoleon. The command of the army was given to the emperor's brother Constantine, a man of somewhat erratic character, who did much to offend the Poles by violence, but also a good deal to please them by his marriage with Johanna Gruzlnska, a Polish lady afterwards created Princess Lowicz, for whose sake he renounced his right to the throne of Russia (see Constantine Pavelovich). The diet met three times during the reign of Alexander, in 1818, in 1820 and in 1825, and was on all three occasions opened by the tsar, who was compelled to address his subjects in French, since he did not speak, and would not learn, their language. It is highly doubtful whether, with the best efforts on both sides, a constitutional government could have been worked by a Russian autocrat, and an assembly of men who inherited the memories and characters of the Poles. In fact the tsar and the diet soon quarrelled. The Poles would not abolish the jury to please the tsar, nor conform as he wished them to do to the Russian law of divorce. Opposition soon arose, and as Alexander could not understand a freedom which differed from himself, and would not condescend to the use of corruption, by which the ancient Polish diets had been managed, he was driven to use force. The third session of the diet—13th of May to 13th of June 1825—was a mere formality. All publicity was suppressed, and one whole district was disfranchised because it persisted in electing candidates who were disapproved of at court. On this occasion, the Poles were told to bow to the failure of constitutional government. They would agitate by means of the so-called National Masonry, or National Patriotic Society as it was afterwards called, for the restoration of the full kingdom of Poland. The nobles who dominated the diet did nothing to remove the most crying evil of the country—the miserable state of the peasants, who had been freed from personal servitude by Napoleon in 1807, but were being steadily driven from their holdings by the landlords. In spite of the general prosperity of the country due to peace, and the execution of public works mostly at the expense of Russia, the state of the agricultural class grew, if anything, worse.

Yet no open breach occurred during the reign of Alexander, nor for five years after his death. The Decembrist movement in Russia had little or no echo in Poland. On the death of Zajoncze in 1826, the grand duke Constantine became Imperial lieutenant, and his administration, though erratic, was not unfavourable to displays of Polish nationality. The Polish army had no share in the Turkish War of 1829, largely, it is said, at the request of Constantine, who loved parades and thought that war was the ruin of soldiers. No attempt was made to profit by the embarrassments of the Russians in their war with Turkey. A plot to murder Nicholas at his coronation on the 24th of May 1829 was not carried out, and when he held the fourth diet on the 30th of May 1830, the Poles made an ostentatious show of their nationality which Nicholas was provoked to describe as possibly patriotic but certainly not civil. Nevertheless, he respected the settlement of 1815. In the meantime the Patriotic Society had divided into a White or Moderate party and a Red or Extreme party, which was subdivided into the Academics or Republicans and the Military or Terrorists. The latter were very busy and were supported by the Roman Catholic Church, which did little for the Prussian Poles and nothing for the Austrian Poles, but was active in harassing the schismatic government of Russia. The outbreak of the French Revolution in 1830 and the revolt of Belgium produced a great effect in Poland. The spread of a belief, partly justified by the language of Nicholas, that the Polish army would be used to coerce the Belgians, caused great irritation. At last, on the 29th of November 1830, a military revolt took place in Warsaw accompanied by the murder of the minister of war, Hauke, himself a Pole, and other loyal officers. The extraordinary weakness of the grand duke allowed the rising to gather strength. He evacuated Warsaw and finally left the country, dying at Vitebsk on the 27th of June 1831 (see Constantine Pavelovich). The war lasted from January till September 1831. The fact that the Poles possessed a well-drilled army of 23,800 foot, 6,800 horse and 128 guns, which they were able to recruit to a total strength of 80,821 men with 135 guns, gave solidity to the rising. The Russians, who had endeavoured to overawe Europe by the report of their immense military power, had the utmost difficulty in putting 114,000 men into the field, yet in less than a year, under the leadership of Diebitsch, and then of Paskevich, they mastered the Poles. On the political and administrative side the struggle of the Poles was weakened by the faults which had been the ruin of their kingdom—faction pushed to the point of anarchy, want of discipline, intrigue and violence, as shown by the abominable massacre which took place in Warsaw when the defeat of the army was known. The Poles had begun by protesting that they only wished to defend their rights against the tsar, but they soon proceeded to proclaim his deposition. Their appeal to the powers of Europe for protection was inevitably disregarded.

When the Congress Kingdom had been reconquered it was immediately reduced to the position of a Russian province. No remnant of Poland's separate political existence remained save the minuscule republic of Cracow. Unable to acquiesce sincerely in its insignificance and even unable to enforce its neutrality, Cracow was a centre of disturbance, and, after Russia, Prussia, and Austria had occupied it also, it was finally occupied by Austria on the 6th of November 1848, as a consequence of the troubles, more agrarian than political, which convulsed Galicia. The administration established by Nicholas I. in Russian Poland was harsh and aimed avowedly at destroying the nationality, and even the language of Poland. The Polish universities of Warsaw and Vilna were suppressed, and the students compelled to go to St Petersburg and Kiev. Polish
recruits were distributed in Russian regiments, and the use of the Russian language was enforced as far as possible in the civil administration and in the law courts. The customs barrier between Lithuania and the former Congress Kingdom was removed, in the hope that the influence of Russia would spread more easily over Poland. A very hostile policy was adopted against the Roman Catholic Church. But though these measures cowed the Poles, they failed to achieve their main purpose. Polish national sentiment was not destroyed, but intensified.

It even spread to Lithuania. The failure of Nicholas was in good part due to mistaken measures of what he hoped would be conciliation. He supported Polish students at Russian universities on condition that they then spent a number of years in the public service. It was the hope of the emperor that they would thus become united in interest with the Russians. But these Polish officials made use of their positions to aid their countrymen, and were grasping and corrupt with patriotic intentions. The Poles in Russia, whether at the universities or in the public service, formed an element which refused to assimilate with the Russians. In Poland itself the tsar left much of the civil administration in the hands of the native officials, but over their peasants was hardly diminished and was misused as of old. The Polish exiles who filled Europe after 1830 intrigued from abroad, and maintained a constant agitation. The stern government of Nicholas was, however, so far effective that Poland remained quiescent during the Crimean War, in which many Polish soldiers fought in the Russian army. The Russian government felt safe enough to reduce the garrison of Poland largely. It was not till 1863, eight years after the death of the tsar in 1855, that the last attempt of the Poles to achieve independence by arms was made.

The rising of 1863 may without injustice be said not to be due to the more humane policy of the tsar Alexander II. Exiles were allowed to return to Poland, the Church was propitiated, the weight of the Russian administration was lightened, police rules as to passports were relaxed, and the Poles were allowed to form an agricultural society and to meet for a common purpose for the first time after many years. Poland in short shared in the new era of milder rule which began in Russia. In April 1836 Alexander II. was crowned king in the Roman Catholic cathedral of Warsaw, and addressed a flattering speech to his Polish subjects in French, for he too could not speak their language. His warning, "No nonsense, gentlemen" (Point de rivières, Messieurs), was taken in very ill part, and it was perhaps naturally, but beyond question most unhappily, the truth that this was a repressive and proscriptions on the Poles, that forced them to resolve to revolt, and to produce a strong Russian reaction against his liberal policy. As the Poles could no longer dispose of an army, they were unable to assail Russia as openly as in 1830. They had recourse to the so-called "unarmed agitation," which was in effect a policy of constant provocation designed to bring on measures of repression to be represented to Europe as examples of Russian brutality. They began in 1860 at the funeral of the widow of General Sobinski, killed in 1830, and on the 27th of February 1861 they led to the so-called Warsaw massacres, when the troops fired on a crowd which refused to disperse. The history of the agitation which culminated in the disorderly rise of 1863 is for the most part intrigue, secret agitation, and in the end of sheer terrorism by a secret society, which organized political assassination. The weakness of the Russian governor, General Gorchakov, in 1861 was a repetition of the feebleness of the Grand Duke Constantine in 1830. He allowed the Poles who organized the demonstration of the 27th of February to form a kind of provisional government. Alongside of such want of firmness as this were, however, to be found such measures of ill-timed repression as the order given in 1860 to the agricultural society not to discuss the question of the settlement of the peasants on the land. Concession and repression were employed alternately. The Poles, encouraged by the one and exasperated by the other, finally broke into the partial revolt of 1863-1864. It was a struggle of ill-armed partisans, who were never even numerous, against regular troops, and was marked by no real battle. The suppression of the rising was followed by a return to the hard methods of Nicholas. The Polish nobles, gentry and Church—the educated classes generally—were crushed. It must, however, be noted that one class of the measures taken to punish the old governing part of the population of Poland has been very favourable to the majority. The peasants were freed in Lithuania, and in Poland proper the great propertyholders were done to death. The government has benefited by their comparative prosperity, and by the incurable hatred they continue to feel for the classes which were once their oppressors. The national history of Poland closes with the rising of 1863.

BIBLIOGRAPHY.—The best general history of Poland is still Józef Szajna's monumental History of Poland according to the latest investigations (4 vols., Pol., Lemberg, 1865-1866), a work which has all the authority of careful criticism and easy scholarship. It adopts, the polonicarum historia (Cracow, 1851) of Joseph Pelczynski, which book has superseded even Joachim Lelewel's learned History of Poland (Pol., Brussels, 1837), of which there are excellent French (Paris, 1844) and German (Leipzig, 1846) editions. The best contemporary general history is August Sokolowski's Illustrated History of Poland (Pol., Vienna, 1896-1900). The best independent German history of Poland is, on the whole, Roeppel (Richard) and Caro's (Jakob) Geschichte Polens (Hamburg and Gotha, 1840-1880). The most comprehensive survey of the Russian history from the 11th century to the 18th have immense fields of research lying open before them in the Acta historica res gestas Poloniae, and in the vol. vii of the First Polish Republic (1872, &c.), and the Historical Dissertations (Pol., 1874, &c.), all three collections published, under the most careful editorship, by the University of Cracow. To the same order belong Ludwik Finkel's Notes sur la polonaise (Paris, 1853), and his Polish Notizen (Leipzig, 1863). The most important work in the field of law is Fr. Maria C. de Tagliani's Codicis Polonicarum historia (2 vols., Warsaw, 1863). The best work in the field of the history of the Church is Steinkopf's Geschichte der polnischen Kirche (Berlin, 1899). The best general work in the field of literature is Wladyslaw Zukowski's History of Literature in Poland (Cracow, 1892). Books on the history of art are too numerous to mention. Among the best are Marchwicki's Geschichte der polnischen Kunst (Berlin, 1894). The best book on Russian influence in Poland is Moes's Geschichte der russischen Einfluss auf Polen (Berlin, 1880).
The Polish language belongs to the western branch of the Slavonic tongues, and exhibits the closest affinities with the Czech or Bohemian and Lusatian Wendish. Unlike the people of other Slavonic countries, the Poles are comparatively poor in popular and legendary poetry, but such compositions undoubtedly existed in early times, as may be seen by the writings of their chroniclers; thus Gallus translated into Latin a poem written on Boleslaus the Brave, and a few old Polish songs are included in Wojciecki's Library of Ancient Writers. A great deal of the early literature written in Poland is in Latin. The earliest specimen of the Polish language is the so-called Psalter of Queen Margaret, discovered in 1826 at the convent of St Florian. The date of the manuscript appears to be the middle of the 14th century, and probably in its present form it is only a copy of a much older text; there is also a translation of the fifteenth psalm belonging to the 13th century. The ancient Polish hymn or war song, Pisan Boga Rodzico, was an address to the Virgin, sung by the Poles when about to fight. The oldest manuscript of this production is dated 1408, and is preserved at Cracow. By a legend which subsequently grew up the composition of it was assigned to St Adalbert. John Lodzia, bishop of Posen from 1335 to 1346, composed several religious songs in Latin.

The next monument of Polish literature to which we come is the Bible of Queen Sophia or Bible of Szaroszpatak. It is imperfect, and only contains the early books, viz. the Pentateuch, Joshua, Ruth and Kings; there are, however, fragments of three others. It is said to have been written for Sophia, the fourth wife of Jagiello, about the year 1455. It has been edited with great care by Malecki. Five religious songs in Polish dating from the 15th century have been preserved; they are ascribed to Andrew Słopuchowski, prior of the monastery of the Holy Cross on Lyssa Góra. There is also the fragment of a hymn in praise of Wycliffe. To these fragments may be added the prayer-book of a certain Wacław, a sermon on marriage, and some Polish glosses. These are all the existing memorials of the Polish language before the 16th century.

Perhaps a few words should be said concerning the writers in Latin. Martin Gallus lived in Poland between 1110 and 1135. From his name he has been supposed by some to have been a Frenchman or Walloon, and we must remember that Poland swarmed at that time with foreign ecclesiastics. Lelewel, the Polish historian, considers that it is merely a translation into Latin of some such name as Kura, signifying a "fowl." Others suppose him to have been an Italian, or a monk from the convent of St Gall in Switzerland. He has plenty of legends to tell us, and writes altogether in a poetical style, so that his prose seems to fall into rhythm unconsciously. His quotations from the classics, Sallust, Lucan and others, show the extent of his reading. Gallus was followed by Matthew Cholewa and Vincent Kadłubek, two bishops of Cracow, and Bohual of Bógwuch of Poland, both of whom are ascribed to this period. The work of Kadłubek is more ornate in diction than that of Bogual, and for a long time enjoyed great popularity. He was born in 1160, educated at the university of Paris, and died in Poland in 1223 as a Cistercian monk. His Latin, like that of Gallus, is far from classical, but he writes with spirit and throws a good deal of light upon the events of his time. The education of the country was wholly in the hands of the ecclesiastics, many of whom were foreigners. We can only explain the great prevalence of the Latin language. Such a system would soon stifle all national outgrowth, and accordingly we have among the Poles none of those early monuments of the language which other countries boast. For instance, there are no blint or legendary poems, such as are found among the Russians, although many passages in the ancient chronicles from their poetical colouring seem to be borrowed from old songs or legends, and the first verses of some of these compositions have been preserved. Mention may here be made of other chroniclers such as Martin the Pole (Polonus), who died in 1279 or 1280, and Jan of Caernow, who died in 1386; the latter was the historian and panegyrist of Casimir IV. His first reign of Casimir III. (1333-1370) must be associated the statutes of Wislica. Jadwiga, the wife of Jagiello, was mainly instrumental in creating the university of Cracow, which received a charter in 1364, but did not come into effective existence till its reconstitution in 1400. In this institution for many years all the great men of Poland were trained—among others Gregory of Sanok, Dlugosz and Copernicus. Casimir the Great may be said to have laid the foundation of this university. Having obtained the consent of Pope Urban V., he established at Cracow a studium generale on the model of the university of Bologna. It consisted of three faculties—Roman law, medicine and philosophy. But the aristocratic youth still preferred frequenting the universities of Prague, Padua, Paris, and accordingly the newly founded studium languished. Jadwiga, however, obtained from Boniface IX. permission to create a new chair, that of theology; and the university of Cracow was remodelled, having been reorganized on the same basis as that of Paris. Another university was founded later at Vilna by Batory, and one at Zamość by the chancellor Zamocky. There were also good schools in various places, such as the Collegium Lubranskio of Posen and the school of St Mary at Cracow. In the year 1473 a press was set up in the latter city, where Günther Zainer printed the first book. The first press from which books in the Polish language appeared was that of Hieronymus Wietor, a Silesian, who commenced publishing in 1515. A few fragments printed in Polish had appeared before this, as the Lord's Prayer in the statutes of the bishops of Breslaw in 1475, the story of Pope Urban in Latin, German and Polish in 1505, &c.; but the first complete work in the Polish language appeared from the press of this printer at Cracow in 1521, under the title, Speeches of the Wise King Solomon. The translation was executed by Jan Koszycy, as the printer informs us in the preface, and the work is dedicated to Anna Wojnicka, the wife of a castellan. In 1522, a Polish translation of Ecclesiastes appeared from that press, and before the conclusion of that year The Life of Christ, with woodcuts, translated into Polish by Balthasar Opec. Many other presses were soon established. Printers of repute at Cracow, during the 16th and beginning of the 17th century, were Sybeneicher and Piotrowczew.

Little as yet had been produced in Polish, as the chroniclers still adhered to Latin; and here mention must be made of Jan Dlugosz, who called himself Longinus. He was bishop of Lemberg, the capital of Galicia, and has left us a very valuable history which has merits of style and shows considerable research. So anxious was Dlugosz to make his work as perfect as he could that he learned Russian so as to be able to read the Chronicle of Nestor. The best part of his book is that which treats of the period between 1386 and 1490. About 1500 was written an interesting little work entitled "Memoirs of a Polish Janissary" (Pamiętniki tsozara polaka). Although written in the Polish language, it was probably the production of a Serb, Michael Constantinovich of Ostrovitza. He was taken prisoner by the Turks in 1455 and served ten years among the Janissaries, after which he escaped into Hungary. About this time also flourished Nicholas Copernicus, a native of Thorn, one of the few Poles who have made themselves known beyond the limits of their country.

The Poles call the period between 1548 and 1606 their golden
age. Poland was the great land of eastern Europe, and owing to
the universal toleration encouraged by the government,
Protestantism was widely spread. Many of the chief nobility
were Calvinists, and the Socini came to reside in the country.
This, however, was to pass away under the great Jesuit re-
action. At Rakow in Poland was published the catechism of the
Socini; to the Jesuits, owing to their persecution, they were
allowed to exist in Poland in 1564, and soon succeeded in getting
the schools of the country into their hands. Besides extirpating
the various sects of Protestants, they also busied themselves
with destroying the Greek Church in Lithuania. Latin poetry
was cultivated with great success by Clement Janicki (1516-1543),
but the earliest poet of repute who wrote in Polish is Rei of
Naglowicz (1593-1650). After a somewhat idle youth he betook
himself to poetry. He was a Protestant, and among other
religious works translated the Psalms. His best work was
Zwiecerzalno albo zwot poczecia polskich (The Mirror or
Life of an Honourable Man)—a somewhat tedious didactic
piece. He was also the author of a kind of play—a mystery
we may term it, and productions of this sort seem to have been
common in Poland from a very early time—entitled Life
of Joseph in Egypt. This piece is interesting merely from an
antiquarian point of view; there is but little poetry in it.
It teems with anachronisms; thus we have mention of the mass
and organs, and also of a German servant. Lucas Goinicki
(1527-1603) wrote many historical works, and Dworzamin
polski, an imitation of the Cortegiano of Castiglione.

Jan Kochanowski (1530-1584), called the prince of Polish
poets, came of a poetical family, having a brother, a cousin
and a nephew who all enriched the literature of
their country with some productions. Kochanowski
studied for some time at the university of Padua,
and also resided in Paris, where he made the acquaintance
of Ronsard. Returning to Poland, he became in 1564 secretary
to Sigismund Augustus. He has left The Game of Chess,
an imitation of Vida, and Proporecz albo hold, pruski (The
Standard or Investiture of Prussia), where he describes the
fealty done by Albert of Brandenburg to Sigismund Augustus.
He also executed a translation of the Psalms. He wrote a
play—a piece of one act, with twelve scenes—The Despatch
of the Greek Ambassadors. It is written in rhymeless five-foot
iambics, and is altogether a product of the Renaissance,
nothing, as of the productions of George Ry shines.
Ry is employed in the choruses only. It was acted
on the marriage of the chancellor Jan Zamoyski with Christine
Radziwill, in the presence of King Stephen and his wife,
at Ujazdowo near Warsaw in 1578. The poet's most popular
work, however, is his Treo or "Lamentations," written
on the death of his daughter Ursula. These beautiful elegies
have been justly praised by Mickiewicz; they are enough to
raise Kochanowski far above the level of a merely artificial
poet. Besides poems in Polish, he also wrote some in Latin.
It will be observed that we get this double-sided authorship
in many Polish writers. They composed for an exclusive and
learned circle, certainly not for the Jew, the German trader
of the West, or the merely illiterate peasant. It may be said
with truth of Kochanowski that, although the form of his poetry
is classical and imitated from classical writers, the matter
is Polish, and there is much national feeling in what he has left
us. Mention must also be made of his epigrams, which he styled
"Trifes" (Fraski); they are full of spirit and genius.
Stanislaw Grochowski (1554-1612) was a priest; but his poetry
is of little merit, although he was celebrated in his time as a
writer of panegyrics. His satire Babie Kolo (The Women's
Circle) gave offence on account of its personalities. A great
partisan of the Catholics in the time of Sigismund III. was
Casimir Minkowski, whose Wlosckie Wziosowanie (a work
well to his native Country) describes the life of the
Szczepan Szarayski, who died young in 1581, deserves notice as having introduced the

sonnet to the Poles. This species of poetry was afterward to
be carried to great perfection by Mickiewicz and Gassznick.

Szymonowicz (1554-1624) was a writer of good pastoral
poems. Although they are imitated from classical writers, he has
introduced many scenes of national life, which he describes
with much vigour. Among the best are
The Lovers, "The Rover," "The Letters on the Seven Sacra-
ments," and "The Lamentations," by which he is
considered one of the best followers of Theocritus. The condition,
however, of the Polish peasants was too miserable to admit of
their being easily made subjects for bucolic poetry. There is an
artificial air about the idylls of Szymonowicz which makes one feel too keenly that they are productions
of the Renaissance; one of their best features is the humane
spirit towards the miserable peasantry which they every-
where display. Another excellent writer of pastoral was
Zimorowicz, a native of Lemberg, who died at the early age
of twenty-five. Some of his short lyrics are very elegant,
and remind us of Herrick and Carew—e.g. that beginning
"Wiekochana Lancellota! Ciebie wie prosto o sioło."
Another writer of pastoral, but not of equal merit, was Jan Gawsinski,
a native of Cracow. Some good Latin poetry was written
by Casimir Sambrowski, better known in the west of Europe
as Sbarievius (d. 1640). He was considered to have approached
Horace more nearly than any other modern poet, and a gold
medal was given him by Pope Urban VIII. Martin Kromer
(1512-1589) wrote a history of Poland in thirty books, and
another volume, giving a description of the country and its
institutions—both in Latin. The history is written in an easy
style and is a work of great merit. A poet of some importance
was Sebastian Fabian Klonowicz (1545-1602), who latinized
his name into Acerinus, Klon being the Polish for maple, and
wrote in both Latin and Polish, and through his inclination
to reform drew down on himself the anger of the clergy.
Sometimes he is descriptive, as in his Polish poem entitled Flis ("The
Boatman"), in which he gives a detailed account of the scenery
on the banks of the Vistula. There is some poetry in this
composition, but it alternates with very prosaic details. In another
piece, Rozalonia, in Latin, he describes the beauties of Galicia.
Occasionally he is didactic, as in Worek Judaszow (The Bag
of Judas) and Victoria doorum, where, under the allegory of
the gods of Olympus, he represents the struggles of parties
in Poland, not without the severity which he inflicts on the nobility
and ecclesiastics. A curious work called Quaestiones
philosophicae, written by Oraczowski (1535-1566), is concerned with
religious polemics. Andrew Mudrowski, a Protestant, in his work De
república commenda (1551), recommended the establishment of a
national church which should be independent of Rome, something
upon the model of the Anglican.

A florid Jesuitical style of oratory became very popular in the
time of Sigismund III., not without rhetorical power, but
frequently becoming tawdry. The chief representa-
tive of this school was Piotr Skarga (1530-1612), one
of the main agents in extirpating Calvinism in Poland and
the Greek Church in Lithuania. Among his numerous writings may
be named Litigation, an extemporaneous and eloquent decla-
rations, and especially his sermons preached before the diet,
in which he lashed the Poles for their want of patriotism and
prophesied the downfall of the country. Mecherzynski, in his
"History of Eloquence in Poland" (Histowia wymowy w Polsce),
especially praises his two funeral sermons on the burial of Anna
Jagiellonka, widow of Stephen Batory, and Anna of Austria, first
wife of Sigismund III. Besides the Latin histories of Wapowski
and Gwagnin (Guagnini, of Italian origin), we have the first
historical work in Polish by Martin Bielski, a Protestant, viz.
Kronika polska, which was afterwards continued by his son.
The author was born in 1495 on his father's estate, Bida, and was
"the first of his family to become a grammarian" at the university of Cracow.
He lived to the age of eighty; but, however great were the merits of his Chronicle, it was long
considered a suspicious book on account of the leanings of the
author to Calvinism. After his death his work was continued

1 His collected works were printed in 1584; there were many
times reprinted, the best edition being that of Warsaw (4 vols.,
1884). His life was written by Przyborowski (Posen, 1857).
his son Joachim (1540-1590). There is also a Chronicle by Bartholomew Papirot. In 1582 was also published the Chronicle of Strzyżków, full of curious learning, and still of great use to the student of history. Five years later appeared the Annales Poloniae of Sarnicki. The last three works are in Latin.

A few words may be said here about the spread of Protestantism in Poland, which is so intimately mixed up with the development of the national language. The doctrines of Hus had entered the country in very early times, and we find Polish recensions of Bohemian hymns; even the hymn to the Virgin previously mentioned is supposed to have a Czech basis. The bishops who suppressed the Hussites were the first to confess, conform to the doctrines of the Roman church. Thus we find that Bishop Andrew of Bnín seized five Hussite priests and caused them to be burnt in the market of Posen in 1430. A hundred years afterwards a certain Katharina Malcher, on account of her Utraquist opinions, was condemned by Gamrat, the bishop of Cracow, to be burnt, which sentence was accordingly carried out in the ragmarket at Cracow. As early as 1530 Lutheran hymns were sung in the Polish language at Thorn. In Königsberg, John Sekucyan, a personal friend of Luther, published a collection of Christian Songs. He was born in Great Poland, and was at first a Roman Catholic priest in Posen, but afterwards embraced the Protestant faith and was invited by Duke Albert as a preacher to Königsberg, where he died in 1578. He executed the first translation of the New Testament in 1531. Four years afterwards appeared a complete Polish Bible published by Scharffenberg at Cracow. In 1555 appeared at Brześć the Protestant translation of the whole Bible made by a committee of learned men and divines, and published at the expense of Nicholas Radziwiłł, a very rich Polish magnate who had embraced the Protestant doctrines. This book is now of great rarity because his son Christopher, having been induced to become a Roman Catholic by the Jesuit Skarga, caused all copies of his father's Bible which he could find to be burnt. One, however, is to be seen in the Bodleian Library, and another in the library of Christ Church at Oxford. A Socinian Bible was issued by Simon Budny in 1570 at Nieświez, as he professed to find many faults in the version issued under the patronage of Radziwiłł; in 1597 appeared the Roman Catholic version of the Jesuit Wujek; and in 1632 the so-called Danzig Bible, which is in use among Protestants and is still the most frequently reprinted.

Up to this time Polish literature, although frequently rhetorical and too much tinctured with classical influences, had still exhibited signs of genius. But now, owing to the introduction and settlement in Poland of the so-called macaronic period, supervision, which lasted from 1666 to 1764, and was a time of great degradation for the language and literature. The former was now mixed with Latin and classical expressions; much of the literature consists of fulsome panegyric, verses written on the marriages and funerals of nobles, with conceits and fantastic ideas, devoid of all taste, drawn from their coats of arms. The poets of this period are, as may be imagined, in most cases mere rhymesters; there are, however, a few whose names are worth recapitulating, such as Wacław Potocki (c. 1622-c. 1666), now known to have been the author of the Wójna Chocimska, or "War of Khotin," the same campaign which afterwards formed the subject of the epic of Krasiński. At first the author was supposed to have been Andrew Lipacki, but the real poet was traced by the historian Szajnocha. The epic, which ran in manuscript till 1850, is a genuine representation of Polish life; no picture so fair appeared till the Pan Tadeusz of Mickiewicz. Moreover, Potocki had the good taste to avoid the macaronic style so much in vogue; his language is pure and vigorous. He does not hesitate to introduce occasionally satirical remarks on the luxury of the times, which he compares, to its disadvantage, with the simplicity of the old Polish life. There is also another poem attributed to Potocki called the New Mercury. In one passage he censures King Michael for ceding Podolia to the Turks. Samuel Twardowski (1600-1660) was the most prolific poet of the period of the Vasas. His most important poem is Władysława IV., King of Poland, in which he sings in a very bombastic strain the various expiditions of the Polish monarch. A bitter satirist appeared in the person of Christopher Opaliński (1609-1656). His works were published under the title of Juvenalis redivivus, and, although boasting but little poetical merit, give us very curious pictures of the times. Hieronymus Vespasian Kołkowski (1635-1699) was a soldier-poet, who went through the campaigns against the Swedes and Cossacks; he has left several books of lyrics full of vivacity, a Christian epic poem, and a Polish psalmody. Another poet was Andrew Michalowski (born about 1620, died about the commencement of the 18th century), an austere courtier, who was finance minister (podskarbi) under John Casimir, and was a devoted adherent of the French party at court, in consequence of which, in the reign of Sobieski, he was compelled to leave his native country and settle in France. His poems are elegant and free from the conceits and pedantry of the earlier writers. In fact, he introduced to Poland the easy French manner of such writers as Boileau. He translated the Cid of Corneille, and wrote a poem on the subject of Psyche, based upon the well-known Greek myth. Poetry in the macaronic period made a backward step; it had been written in the Polish language in its golden age; it was now again to take a Latin form, as in the Chronica Gestarum in Europae singularium of the ecclesiastical Paul Piascik (1580-1649), who is an authority for the reigns of Sigismund III. and Wladislaus IV., and Rudowski, who describes events from the accession of John Casimir to his death in 1578; and as valuable materials for history may be mentioned the five huge volumes of Andrew Chryssostom Zaluski (1711), bishop of Warmia. This work is entitled Epistolae historico-familiares. It would be impossible to recapitulate here the great quantity of material in the shape of memoirs which has come down, but mention must be made of those of John Chrystostom Pasek, a nobleman of Mosovia, who has left us very graphic accounts of life and society in Poland; after a variety of adventures and many a well-fought battle, he returned to the neighbourhood of Cracow, where he died between 1669 and 1701. Some of the most characteristic stories illustrating Polish history are drawn from this book. A later period, that of the miserable epoch of Augustus III., is described very graphically in the memoirs of Matuszewicz, first edited by Pawinski at Warsaw in 1786. Relating to the same period are also the memoirs of Bartholomew Michałowicz (Pamiętniki Barłomieja Michałowskiego). A curious insight into the course of education which a young Polish must have undergone is given by those addresses to the students which James Sobieski, the father of the celebrated John, gave to Orkowsky, the tutor of his sons. This has been twice printed in comparatively recent times (Instrucytu Jakob Sobieskigo kosztelana Krakowskiego dana panu Orkowskiemu se strony synów, Vilna, 1840). The old gentleman in his aristocratic impropriety frequently reminds us of the amusing directions given by Sir John Wynn to his chaplain, quoted in Pennant's Tour in Wales.

A History of the Lithuanians in Latin was published by the Jesuit Koiwałowicz; the first volume appeared at Danzig in 1650. A valuable work on the condition of Poland was written by Stanislaus Leszczynski, who, was twice chosen king, entitled Gedan widný wydaný wiedzącacy (A Free Voice Guaranteeing Freedom), where he tells the Poles some homely and perhaps disagreeable truths illustrating the maxim Summa libertas etiam perire volubilis. A notable man was Joseph Andrew Żaluski, bishop of Kiev, a Pole who had become thoroughly Frenchified—so much so, that he preached in French to the fashionable congregations of Warsaw. He collected a splendid library of about 300,000 volumes and 15,000 manuscripts, which he bequeathed to the Polish nation; but it was afterwards carried off to St. Petersburg, where it formed the foundation of the imperial public library. According to Nitschmann in his Geschichte der polnischen
Littérature—a work which has been of service in the preparation of this article—the books were transported to Russia very carelessly, and many of them injured by the way. It was especially rich in works relating to Polish history. Konarski edited in six volumes a valuable work entitled Volumina sive, containing a complete collection of Polish laws from the time of the statute of Wielchi. He did much good also in founding throughout the country schools for the education of the sons of the upper classes, but as yet nothing had been done for popular education properly so-called. About the close of this period we have some valuable writers on Polish history, which now began to be studied critically, such as Hartknoch in his All-und Neues Preussen (1684), a work in which are preserved interesting specimens of the old Russian language, and Lengnick (1680–1774), author of the valuable Justinianus regni Poloniae, which appeared in 1742.

We now come to the reign of the last Polish king, Stanislaus Poniatowski, and the few quiet years before the final division of the country, during which the French taste was all-powerful. This is the second great period of the development of Polish literature, which has known nothing of medieval romanticism. The literature of the first or Renaissance period gives us some good poets, who although occasionally imitators are not without national feeling, and a goodly array of chroniclers, most of whom made use of Latin. In the second or French period we get verse-makers rather than poets, who longed for Frenchmen, and sigh over the barbarism of their country; but the study of history in a critical spirit is beginning under the influence of Naruszewicz, Albertrenzi and others. In the third period, that of modern romanticism, we get true nationalism, but it is too often the literature of exile and despair. Here may be mentioned, although living a little time before the reign of Stanislaus, a Polish poetess, Elizabeth Druzbacka (1695–1760), whose writings show a feeling for nature at a time when verse-making of the most artificial type was prevalent throughout the country. The portrait prefixed to the Leipzig edition of her works is a striking one, representing a handsome, intellectual-looking woman, dressed in the garb of some religious order. Her Life of David in verse appears tedious, but many of the descriptions in the Seasons are elegant. Unfortunately she introduces latinitisms, so that her Polish is by no means pure. A national theatre was founded at Warsaw in 1765 under the influence of the court, but it was not till long afterwards that anything really national connected with the drama appeared in Poland. Thomas Kajetan Węgierski (1755–1787), who was chamberlain to the king, enjoyed a considerable reputation among his countrymen for his satirical writing. He was a kind of Polish Churchill, and like his English parallel died young. His life also appears to have been as irregular as Churchill's. In consequence of an attack on the empress of Russia, he was compelled to leave Poland, and accordingly made a tour in Italy, France, America, and England, dying at Marseilles at the early age of thirty-three. His poetry shows the influence of the French taste, then prevalent throughout Europe. In times of great national disasters he deserves to be remembered as a true patriot; but the spirit of his poetry is altogether unwholesome. It is the wailing cry of a moribund nation. The great laureate of the court of Stanislaus was Trembecki (1722–1812), whose sympathies were too much with the Russian invaders of his country. He was little more than a fluent poetaster, and is now almost forgotten. One of his most celebrated pieces was Zofjeusza, written on the country seat of Felix Potocki, a Polish magnate, for this was the age of descriptive as well as didactic poetry. Perhaps the English gave the hint in such productions as "Cooper's Hill." The old age of Trembecki appears to have been ignoble and neglected; he had indeed "fallen upon evil days and evil tongues"; and when he died at an advanced age all the gay courtiers of whom he had been the parasite were either dead or had submitted to the Muscovite yoke. He comes before us as a belated epicurean, whose airy trifles cannot be warbled in an atmosphere surcharged with tempests and gunpowder.

The end of the 18th century was not the period for a court poet in Poland. The most conspicuous poet, however, of the time was Ignazius Krasicki, bishop of Warmia (1735–1801). He was the friend of Frederick the Great and a prominent member of the king's literary club at Sans Souci. Krasicki wrote an epic on the war of Khotin—the same as had furnished the subject of the poem of Potocki, of which Krasicki in all probability had never heard, and also that of the Dalmatian Gundulich. Krasicki's poem is at best but a dull affair, in fact a pale copy of a poor original, Le Héritage de Voltaire. His mock heroes are, to say the least, amusing, and among these may be mentioned Jezus, where he describes how King Popiel, although belonging to the legend, was, in fact, the poet himself. Konarski mache is in six cantos, and is a satire upon the monks. The bishop was also the writer of some pretty good comedies. In fact most styles of composition were attempted by him—of course satires and fables among the number. He presents himself to us much more like a transplanted French abbe than a Pole. In the year 1801 he travelled to Berlin, and died there after a short illness. Among his other works the bishop published in 1781–1782, in two volumes, a kind of encyclopaedia of belles lettres entitled Œuvres philosophiques. His estimates of various great poets are not very accurate. Of course he finds Shakespeare a very "intelligent" author, although he is willing to allow him considerable praise for his humour. F. Morawski (1753–1861) published some excellent Fables (1800) in the manner of Krasicki, and in 1831 an epic entitled My Grandfather's Farm. Adam Naruszewicz (1733–1796) was bishop and poet. The existence of so many ecclesiastical writers was a natural feature in Polish literature; they formed the only really cultured class in the community, which consisted besides of a haughty ignorant nobility living among their serfs, and (at a vast distance) those serfs themselves, in a brutalized condition. Burghers there were, properly speaking, none, for most of the citizens in the large towns were foreigners governed by the Jus Hamburgicum. Naruszewicz has not the happy vivacity of Krasicki; he attempts all kinds of poetry, especially satire and fable. He is at best but a mediocre poet; but he has succeeded better as a historian, and especially to be praised is his "History of the Polish Nation" (Historia narodu polskiego), which, however, he was not able to carry further than the year 1386. He also wrote an account of the Polish general Chodkiewicz, and translated Tacitus and Horace. Interesting memoirs have been published by Kilinski, a Warsaw shoemaker, and Kosmin, state referendary, who lived about this time and saw much of the War of Independence and other political affairs. Among the smaller poets of this period may be mentioned Karpinski (1741–1829), a writer of sentimental elegies and ballads, in the style then so very much in fashion, and Franczyk Dysonzy Kniażnin (1750–1807), who nourished his muse on classical themes and wrote several plays. He was the court poet of Prince Adam Czartoryski at Pulawy, and furnished odes in commemoration of all the important events which occurred in the household. He lost his reason on the downfall of Poland, and died after eleven years' insanity in 1807. Julian Ursyn Niemcewicz (1758–1841) was one of the most popular of Polish poets at the commencement of the present century (see Niemcewicz). His most popular work is the "Collection of Historical Songs" (Pieśni historyczne), where he treats of the chief heroes of Polish history. Besides these he wrote one or two good plays, and a novel in letters, on the story of two Jewish lovers; John Paul Woronzow (1757–1834), born in Volhynia, and at the close of his life bishop of Warsaw and primate of Poland, was a very eloquent divine, and has been called the modern Skarga. A valuable worker in the field of Slavonic philology was Linde, the author of an excellent Polish dictionary in six volumes. For a long time the cultivation of Polish philology was in a low state, owing to the prevalence of Latin in the 17th century and French in the 18th. No Polish grammar worthy of the name appeared till that of Kopczyński at the close of the 18th century, but the reproach
has been taken away in modern times by the excellent works by Malecki and Malinowski. Rakowiecki, who edited the *Rozwadowskie Przedsiebiorstwo*, and Maciejewski (who died in 1883, aged nineteen) have brought the Slavonic law, may here be mentioned. Here we have a complete survey of the leading codes of Slavonic jurisprudence. At a later period (1856) appeared the work of Helcel, *Starodawnre prawa polskiego pomniki* ("Ancient Memorials of Polish Law"). Aloyius Feliński (1771-1820) produced an historical tragedy, *Barbara Radziwiłł*, and some good comedies were written by Count Polish

Drame. Alexander Fredro (1793-1876). In fact Fredro may be considered the most entertaining writer for the stage which Poland has produced. He introduced genuine comedy among his countrymen. The influence of Molière can be very clearly seen in his pieces; his youth was spent chiefly in France, where he formed one of the soldiers of the Polish legion of Napoleon and joined in the expedition to Russia. His first production was *Pan Gedda*, written in 1819 and produced at Warsaw in 1821. From 1819 to 1835 he wrote about seventeen pieces and then abandoned publishing, having taken offence at some severe criticisms. At his death he left several comedies, which were issued in a posthumous edition. There is a good deal of local colouring in the pieces of Fredro; although the style is French, the characters are taken from Polish life. From him may be said to date the formation of anything like a national Polish theatre, so that his name marks an epoch. The Poles, like many of the other nations of Europe, had religious plays at an early period. They were originally performed in churches; but Pope Innocent II. finding fault with this arrangement, the acting was transferred to churchyards. Mention has already been made of plays written by Rej and Kochanowski; they are mere fruits of the Renaissance, and cannot in any way be considered national. The wife of John Casimir, a Frenchwoman, Marie Louise, hired a troop of French actors and first familiarized the Poles with something which resembled the modern stage. The Princess Franciszka Radziwiłł composed plays which were acted at her private residence, but they are spoken of as inartistic and long and tedious. The national theatre was really founded in the reign of Stanislaus Augustus; and good plays were produced by Bohomolec, Kamiński, Kropiński, Boguslawski, Zabocki, and others. Perhaps, however, with the exception of the works of Fredro, the Poles have not produced anything of much merit in this line. A great statesman and writer of the later days of Polish nationality was Kolłąta, born at Sandomir in 1750. He was a man of liberal sentiments, and, had his plans been carried out, Poland might have been saved. He wished to abolish serfdom and throw open state employments to all. The nobility, however, were too intimated to be willing to adopt these wise measures. Like the French aristocrats with the reforms of Necker, they would not listen till ruin had overtaken them. During the last war of Poland as an independent country Kolłąta betook himself to the camp of Kościusko, but when he saw that there was no longer hope he went to Galicia, but was captured by the Austrians and imprisoned at Olmütz till 1803. He died in 1812. An active co-operator with Kolłąta was Salesius Jeziorski, who founded clubs for the discussion of political questions, and Stanislaus Staszic, who did much for education and improved the condition of the university of Warsaw.

The reputation of all preceding poets in Poland was now destined to be thrown into the shade by the appearance of Mickiewicz (1798-1855), the great introductor of romanticism into the country (see Mickiewicz). He was born in Warsaw, and was educated in the Polish legion, and has left a small collection of poems, the most important being the idyl *Wieś*, in which the manners of the peasants of the district of Cracow are faithfully portrayed. The second greatest poet of the romantic school who appeared in Poland after Mickiewicz was Julius Slowacki (1809-1849), born at Krzemieniec. In 1831 he left his native country and chose Paris as his residence, where he died. His writings are full of the fire of youth, and show great beauty and elegance of expression. We can trace in them the influence of Byron and Victor Hugo. He is justly considered one of the greatest of the modern poets of Poland. His most celebrated pieces are *Hugo; Mnich* ("The Monk"); *Lambro*, a Greek corsair, quite in the style of Byron; *Ankelli*, a very Dantesque poem expressing under the form of an allegory the sufferings of Poland; *Krol duch* ("The Spirit King"), another mysterious and allegorical poem; *Wadow*, on the same subject as the *Marya* of Malczewski, to be afterwards noticed; *Bentowski*, a long poem in ottava rima on this strange adventurer, something in the style of Byron's humorous poems; *Kordyan*, of the same school as the English poet's *Manfred*; *Lila Weneda*, a poem dealing with the early period of Slavonic history. The life of Slowacki has been published by Professor Anton Malecki in two volumes. Mickiewicz and Slowacki were both more or less mystics, but even more we may assign this characteristic to Sigismund Krasinski, who was born in 1812 at Paris, and died there in 1859. It would be impossible to analyse here his extraordinary poem *Nieboska komedja* ("The Undivine Comedy"), *Irydion*, and others. In them Poland, veiled under different allegories, is always the central figure. They are powerful poems written with great vigour of language, but enveloped in clouds of mysticism. The life of Krasinski was embittered by the fact that he was the son of General Vincent Krasinski, who had become unpopular among the Poles by his adherence to the Russian government; the son wrote anonymously in consequence, and was therefore called "The Unknown Poet." Among his latest productions are his "Psalms of the Future" (*Psalmy przyszłości*), which were attacked by the democratic party as a defence of aristocratic views which had already ruined Poland. His friend Slowacki answered them in some taunting verses, and this led to a quarrel between the poets. One of the most striking pieces of Krasinski has the title "Resurrecturis." The sorrows of his country and his own physical sufferings have communicated a melancholy tone to the writings of Krasinski, which read like a dirge, or as if the poet stood always by an open grave—and the grave is that of Poland. He must be considered as, next to Mickiewicz, the greatest poet of the country. Other poets of the romantic school of considerable merit were Gorecki, Witwicki, Odyneic, and Gaszynski; the last-named wrote many exquisite sonnets, which ought alone to embalm his name. Witwicki (1800-1847) was son of a professor at Krzemieniec. He was a writer of ballads and poems dealing with rural life, which enjoyed great popularity among his countrymen and had the good fortune to be set to music by Chopin. The works of Lelewel have separate mention (see LELEWEL); but here may be specified the labours of Narbutt, *Dzieje starożytnej Polski* ("Early History of the Lithuanian People"), published at Vilna in nine volumes, and the valuable *Monumenta Poloniae historica*, edited at Lemberg by Biciowsky, of which several volumes have appeared, containing reprints of most of the valuable documents. Lelewel died in 1876.

A further development of romanticism was the so-called *Ukraine* school of poets, such as Malczewski, Gozczynski, and Zaleski. Anton Malczewski (1793-1826) wrote one poem, *Marya*, a Ukrainian tale which passed unannounced at the time of its publication, but after its author's death became very popular. Malczewski was one of Napoleon's officers; he led a wandering life and was intimate with Byron at Venice; he is said to have suggested to the
The latter story of Mazeppa. Myrza is a narrative in verse in the manner of Byron. It is written with much feeling and elegance, and in a most harmonious metre. The chief poem is Szeravin Gosczyński (1805-1866) is Zamek Kaniówski ("The Tower of Kanion"). The most interesting poem of Bogdan Zaleski (1810-1859) is the "Spirit of the Song" (Dwadzieścia siedem). Other poets of the so-called Ukraine school, which has been so well inspired by the romantic legends of that part of Russia, are Thomas or Timko Padoua (who also wrote in the Malo-Russian, or Little-Russian, language), Alexander Groza, and Thomas Oliarowski. For many of the original songs and legends we must turn to the work of Messrs Antonovich and Dragomanov. Bogdan Joseph Zaleski was born in 1802 in the Ukraine village, Bohaterka. In 1830 he was sent to the university of Warsaw, where he had Gosczyński as a fellow student. Besides the longer poem previously mentioned, he is the author of many charming lyrics in the style of the Polish peasant songs, such as Shevchenko has written in that language. He died at Villepreux, in France, in 1886, after more than fifty years of exile. Michael Grabowski (1805-1863) belongs also to this school by his fine Melodies of the Ukraine (1828). Maurice Glosławski also won fame by his Poems of a Polish Outlaw in the struggle of 1830-1831. A poet of great vigour was Stephen Garchynski (1806-1833), the friend of Mickiewicz, celebrated for his War Sonnets and his poem entitled The Doeds of Wadow.

Wincenty Pol (1807-1872) was born at Lublin, and though of foreign extraction by both parents proved an ardent patriot. He wrote a fine descriptive work, Obraz z życia i podróży ("Pictures of Life and Journey") in 1836. He also a collection of "The Landscape of our Land ". For about three years from 1849 he was professor of geography in the university of Cracow. In 1855 he published Jako Polska ("As a Pole"); the following volumes of Stanislau Poniatski, Ludwik Wladyslaw Kondratowicz (who wrote chiefly under the name of Syrokomla) was born in 1823 in the government of Minsk, and died on the 15th of September 1850 at Vilna. His parents were poor, and received a very meagre education; and consequently for it he was a careful self-culture. One of his most remarkable poems is his Jan Dębarog, in which, like Mickiewicz, he has well described the scenery of his native Lithuania. He everywhere appears as the advocate of the suffering peasants, and has contributed much not only for it but also to the cause of the beautiful. In Kaczkowski the Poles found a novelist who treated many periods of their history with great success. His sympathies, however, were mostly aristocratic, though modified by the desire of progress. An important writer of history is Karl Szajnocha (1818-1868), born in Galicia of Czech parents. He began his labours with The Age of Casimir the Great (1848), and Bolehowski and Saxon Kings, of which these volumes (1853-1856) were a work which Sapovich, in his Russian History of Slavonic Literature, compares in vigour of style and fullness of colour with Macaulay's History of England and Thierry's Norman Conquest. Szajnocha was still a young writer in a great misfortune; from overwork he lost his sight in 1857. Szajnocha, however, like Thierry and the American Prescott, did not abandon his studies. His excellent memory helped him in his absence; he published a work in which he traced the origin of Poland from the Varangians (Lechicki początek polski), thus making them identical in origin with the Russians. He began to write the history of John Sobieski, but did not live to finish it. Died in 1868, soon after completing a history of the Cossacks Dwa lata dziejów nieszcy ("Two Years of Our History "). A writer of romances of considerable power was Joseph Korzeniowski (1797-1865), tutor in early youth to the poet Krasiński, and afterwards director of the school at Krakow. Korzeniowski, died in 1868, and was author of some popular novels, such as Wdzieksu orygina ("Tours of an Original "), 1848; Garbaty ("The Hunchback "), 1852; and the novel of Mieszko (1851). His works constitute a library in themselves; they are chiefly historical and political novels, some or which treat of early times in Poland, and some of its condition under the Saxon kings. A few of these, translated into English, have appeared in our language. He was a poet of much power, and wrote, at least for the time, was chiefly lyrical. Other writers deserving mention are Cornelius Ujspijski (1823-1897), the poet of the last revolt of 1863; Theophilus Letarowicz (born 1822), who wrote some very graceful poetry; Stefan Niemcewicz (1823-1869), who has been drawn from Polish history, for the novel of the school of Sir Walter Scott still flourishes vigorously among the Poles. Among the novel writings of which romances may be mentioned Henry Rzewuski (1791-1866); Joseph Dziekoński wrote Wodecki, a romantic life, and Michael Czajkowski (1808-1876) romances of the Ukraine; Valerius Wieloglowski (1865) gave pictures of country life.

In 1882 the Poles lost, in the prime of life, a very promising historian Szujski (born in 1835), and also Schmitt, who died in his sixty-sixth year. Szujski commenced his literary career in 1859 and devoted himself to the study of the production. Rzota na Historie Polski ("A Glance at Polish History "), which attracted universal attention; and in 1862 he commenced the History of Poland ("Z dziejów Polski "), the printing of which ceased in 1866. The value of this book is great both on account of the research it displays and its philosophical and unprejudiced style. One of the last works of Szujski written in collaboration was The History of the Earlier Times to the year 1763 (1854), History of Poland in the 18th and 19th Centuries (1866), and History of Poland from the time of the Partitions (1868), which he carried down to the year 1832. In opposition to the opinion of many historians, his contemporaries, that Poland fell through the nobility and the diets, Schmitt held that the country was brought to ruin by the kings, who have surrendered to the French and the Swedes, and were led away to the pernicious influence of the Jesuits. Adalbert Kętrzyński, who succeeded Bielowski in 1877 in his post of director of the Ossolinski Institute at Lemberg, is the author of some valuable monographs on Polish literature. The last works of Polish literature which have treated of the history of the Jagellons; and Szańczewicz, professor at the university of Lemberg, has written on the early history of Galicia. Thaddeus Wojciechowski has published a clever work on the rise of the Polish language and literature. Of the national literature, in 1836, after a period of exile, the return of the National subscription of manuscripts in the Jagellon library at Cracow. Dr Joseph Kasimir Pfefferkorn, besides editing the Bibliography of Polish literature, a very valuable library journal which stands at the head of all works of the same kind in Poland, has published essays on the literary history of the liberum veto, which puts that institution in a new light. Felix Jezierski, the previous editor of the above-mentioned journal, has in a translation of parts of Homer, and is also the author of an excellent work on German Literature. The history of Polish literature has not been neglected. We have already the early history of Felix Bentkowski (1781-1852), followed by that of Michael Wiazemsky (1794-1865), which, however, only extends to the 17th century, and is at best but a quarry of materials for subsequent writers, the style being very heavy. A History of Eloquence ("Historia wymowy w Polsce") was published by Władysław Morczyński. An elaborate history of Polish literature has been written by Anton Malecki, who is the author of the best Polish grammar (Gramatyka historyczno-porównawcza języka polskiego, 2 vols., Lemberg, 1879). The Polish bibliography of John Mieszko, a work which has become the classic of its kind, is of the highest importance. One of the most active writers on Polish philology and literature is Władysław Nehrung, whose numerous contributions to the Archiv für slawische Philologie of Professor Jacek entitle him to the gratitude of all who have devoted themselves to Slavonic studies. Wladimir Spasowicz, a lawyer of St Petersburg, assisted Pipin in his valuable work on Slavonic literature. The first part of Pipin's book has appeared in the Polish, and the second part has been translated into English. The first half of the 19th century are written with much spirit and appreciation. The larger poetical works which appear during that time are carefully analysed. The times of the most interesting geological and anthropological investigations have been carried on in Poland. In 1868 Count Constantine Tyszkiewicz published a valuable monograph on the Observation of Lithuanian and Western Ruthenia, and Professor Joseph Tegethoffer has greatly enriched the ethnography museum of his native city. In philosophy the Poles (as the Slavs generally) have produced but few remarkable names. Goluchowski, the brothers Andrew and Michael, Józef Taborowski, and Jan Nepomucen Taborowski, who have been of considerable European, Bronisław Trentowski, Karel Liebelt and Joseph Kremser
POLAND, RUSSIAN

deserve mention. August Cieszkowski has written on philosophical and economic subjects. Moritz Straszewski, professor of philosophy at the university of Cracow, has also published some remarkable works.

Mention has already been made of the poetess Elizabeth Druszka. Female writers are not very common among Slavonic nations. Perhaps the most celebrated Polish authoress was Klementyna Hofman, whose maiden name was Tucholska, born at Warsaw, in 1798. She married Karl Boromius Hofman, and accompanied him, in 1831, to Passy near Paris, where she died in 1845. Her name is still remembered in Polish literature. The prose and poetry of Caroline Kielewka, born in Cracow, in 1835, has also been very favourably noticed. Mention must also be made of Balucki (1837-1901), author of novels and comedies, and Narzynski (1839-1872), who was educated in France, but spent part of his short life in Cracow, author of some very popular tales.

The four centres of Polish literature, which, in spite of the attempts which have been made to denationalize the country, is failing to be so, are Cracow, Pozen, Lemberg, and Warsaw. A cheap edition of the leading Polish classics, well adapted for dissemination among the people, has been published, under the title of Biblioteka Polska, at Cracow. Not only are the professors of Cracow University some of the most eminent living Poles, but it has been chosen as a place of residence by many Polish literary men. The academy of sciences, founded in 1782, celebrated the bicentenary of the raising of the siege of Vienna by Sobieski by publishing the valuable Acta Academiae Cracoviensis. Some good Polish works have been issued at Pozen. At Lemberg, the capital of Austrian Galicia, there is an active Polish press. Here appeared the Monumenta Poloniae historica, of Hebenstreit, previously mentioned; but Polish in this province has to struggle with the Red-Russian or Ruthenian, a language or dialect which for all practical purposes is the same as the Southern or Little Russian. At Warsaw, since the last insurrection, the Polish press has become active, and many of the Polish novels and plays are published in Russian; but Polish works of merit still issue from the press—among others the leading Polish literary journal, Biblioteka warszawska.

Perhaps the most popular modern writer in Poland is Eliza Orzeszkowa, of whose novels a complete "Jubilee" edition has appeared. Many of her tales—as, for instance, Argonauci (“The Argonauts”)—have appeared in the Tygodnik, or weekly illustrated journal of that name. Orzeszkowa has enjoyed great success in Russia. The object of this tale is to bridge over the gulf between the Jew and Christian in Poland. Adolf Dygasiński writes clever village tales of the "kailyard" school, as it has been sometimes termed in England. Sienkiewicz has enjoyed great popularity in the Land of the Jokuts, a contribution to the literature of folklore and ethnology such as only a real artist could produce. Among the latest writers in Polish are Wyspianski, Kisielewski, Reymont, Mme Zopalska; the latter is the author of some charming novels and plays, and she has been called the Polish Zola. It is this kind of poetry and traces of the decadent school which we find in the later Polish poets. A pessimistic spirit is apparent, as in the writings of Wenceslaus Berent. Since the death of Asnyk and Uljejski the most prominent poet is Marya Konopnicka (1836). Some good critical work has been done in the leading reviews by Swiatochowski and others. Historical work has been produced by Hirschberg, Pappe, Sobieski, Czermak and others, and the histories of Polish literature by Stanislaus Tarnowski and Piotr Chmielewski are of the highest value, the former dealing more with the past, and the latter with the historical character of the Poles as it is today. Hence the enthusiasm for historical studies, and the Biblioteka pisarzyw polskich, which shows us what abundance of literature was produced in Poland in the 16th and beginning of the 17th century. In Henryk Sienkiewicz (g.v.), the historical novelist, Poland has a modern writer of European reputation.

Frederick and Spalowich, Istoria slawianskikh literatur (in Russian; St Petersburg, 1879); Geschichte der polnischen Literatur von Dr. A. Brückner (Leipzig, 1901; also written in Polish); Chmielewski, History of Polish Literature (in Polish, 3 vols.); Stanislaus Tarnowski, History of Polish Literature (in Polish); Grabowski, Powszechna Polska po roku 1883 (Cracow, 1903); Heinrich Nitschmann, Geschichte der polnischen Literatur (Leipzig; eine ann.). (W. R. M.)

POLAND, RUSSIAN, a territory consisting of ten governments which formerly constituted the kingdom of Poland (see above), but now are officially described as the "governments on the plateau of plateaus, which merge imperceptibly into the northern spur of the Carpathians. These plateaus, with an average elevation of 800 to 1000 ft., are mostly covered with forests of oak, beech and lime, and are deeply cut by river valleys, some being narrow and craggy, and others broad, with gentle slopes and marly bottoms. Narrow ravines intersect them in all directions, and they often assume, especially in the east, the character of wild, impassable, woody and marshy tracts. In the south-eastern corner of Poland they are called podlasie, and are in a measure akin to the polyesie of the Pripyat. The Vistula, which skirts them on the south-west, cuts its way through them to the great plain of Poland, and thence to the Baltic. Its valley divides the hilly tracts into two parts—the Lublin heights on the east, and the Sandomierz (Sandomierz) or central heights on the west. These last are diversified by several ranges which run east-south-east, parallel to the Beskides of the Carpathian system, and are the highest of them being the Lyda Gora, which reach 1910 ft. and 2010 ft. above the sea. Another short ridge, the Chcinski hills in Kielce, follows the same direction along the Nida river and reaches 1345 ft. south of the Nida; the Olkusz hills, linked on to the spurs of the Beskides, fill up the south-west corner of Poland, reaching 1620 ft., and containing the chief mineral wealth of the country; while a fourth range, 1000 to 1300 ft. high, runs north-west past Czesczotaw, separating the Oder from the Warta (Warthe). In the north, the plain of Poland is bordered by a flat, broad swelling, 600 to 700 ft. above the sea, dotted with lakes, and recalling the lacustrine regions of northern Russia. Wide tracts of sand, marshes, peat-bogs, ponds, and swamps exist, through which the streams freely meander from one marsh to another, the whole covered with thin pine-forests and scanty vegetation, with occasional patches of fertile...
group of small lakes is situated in the basin of the Warta (north part of Kalisz), the largest being Gojło, 18 m. long and 100 ft. deep.

Climate.—With the exception of the Lysa Góra hilly tracts (between the Vistula and the southern frontier), which lie between the isotherms of 4° and 42°, Poland is situated between the isotherms of 42° and 46°. The isotherces and isoleths (i.e. lines of equal mean summer and winter temperature respectively) crossing one another at right angles, and the former running east-north-east, the latter east-south-east, the quantity increases slowly towards the south on account of the proximity of the Carpathians, where it is 30.3°. Owing to this distribution, the snow-sheet in Poland is not very thick, and spring sets in early. Strollers from 2 to 22° (February and March), and the rivers are generally icebound for two or a half to three months—the Warta being under ice for 70 to 80 days, the Vistula at Warsaw for 80 days (and especially) even for 116, and the Memel for 100 (exceptionally for 140).

The following averages will serve to illustrate the climate of Poland:

Flora.—The flora of Poland is more akin to that of Germany than to that of Russia, several middle European species finding their way across the Prussian limits in the southern part of Lithuania. Coniferous forests, consisting mostly of pine (Pinus sylvestris) and birch, cover large tracts in Mazovia in the north, and across the Baltic lake-ridge southwards as far as the confluence of the Vistula and the Narew, and join in the south-east the Polisye of the Pripet. The pine covers the Lysa Góra hills and the hills in the extreme south-west. The larch, which centuries ago covered large tracts, has almost entirely disappeared. Pinus silvestris is only remembered, as also Taxus baccata. Ficus benghalensis is cultivated.

Of deciduous trees, the common beech is the most typical; it extends from the Carpathians to 52° N., and reaches three degrees farther north in small groups or isolated specimens; the conifer of the Bug and the Narew may be regarded as its eastern limit. The white beech (Carpinus betulus), the aspen, and two elms (Ulmus carpinifolia, U. oficiolata) are found nearly everywhere. The lime (Tilia) reaches its maximum in the Vistula basin. The birch (Betula pendula) is the most popular tree with the Poles, as the birch with the Russians; judgment of old was pronounced under its shade, and all the folk-songs extol it. Of all its natural habitats, the birch is highly cultivated tree in Poland, though not so much as in Lithuania—grows in forests only on the most fertile land, but is of common occurrence in conjunction with the beech, elm, &c. The maples (Acer platanoides and A. pseudo-platanus), and some other species, thrive at the banks of the rivers and canals, and the Alnus incana is common. The willow and orchard trees—apple, pear, plum and cherry—are cultivated everywhere.

Fauna.—The fauna of Poland belongs to the middle European zoological group; within the historical period it has lost such species as formerly gave it a subarctic character. The reindeer now occurs only as a fossil; the sable, mentioned in the annals, has migrated eastwards; the wild horse, described at the time as having the size of a great horse, has been in Poland since the thirteenth century, and is still common in the western part of the country. The wild boar, the wolf, the wild bear, and the fox are most common throughout the greater part of the country; as in the case of the hare and several species of Arvicolinae. The mammals in Poland, however, do not exceed fifty species. The avian fauna, which does not differ greatly from that of central Europe, is represented by the naturalists of thirty-six and twenty species, among which the singing birds (Dinuclerostris and Coniostra) are the most numerous. On the whole, Poland lies to the westward of the most frequented route of the migratory birds, and has in its less wild and more restless state of conditions most of common Russia. Numerous aquatic birds breed on the waters of the Baltic lake-region.

Population.—The population of Poland, 6,103,710 in 1871, reached 7,319,980 in 1881, and 10,500,000 in 1897. The estimated population in 1906 was 10,747,350. Details for 1887 are shown in the subjoined table.
The non-domiciled population numbered about 1,000,000, and by 1904 the total was estimated to have increased to 12,000,000, the ratio between the two from 1884 having been 40-6. Poland, with 193 (domiciled) inhabitants or 213 inhabitants in all to the square mile in 1897, and 240 to the square mile in 1904, has a denser population than any other province in the Russian empire, the next to it being the governments of Moscow, with 185 inhabitants to the square mile, Podolia with 186, and Kiev with 181. The drift townsward of the rural population began in 1890, when the urban population amounted to only 18% of the whole, whereas in 1904 it reached 24% and the population of Warsaw and other cities was substantially augmented. In a whole. Of the towns of Poland 32 have a population each exceeding 10,000, the largest being Warsaw the capital, with 635,208 inhabitants in 1904, followed by Lodz with 315,852, Pinsk with 304,756, and Riga with 351,570 in 1900; Czestochowa, with 45,130 in 1897 and 53,690 in 1900; and Lublin, with 50,152 in 1897. According to nationalities, the population was made up as follows in 1897: 6,755,503 Poles, equaling 74.8% of the total; 2,588,442 Russians (6%); 631,844 Lithuanians (6%); 391,440 Germans (4%); 310,368 Lithuanians and Letts (5%); with a few thousands each of Tatars, Bohemians, Rumanians, and Estonians, and a few Gypsies and Hungarians.

During prehistoric times the basin of the Vistula seems to have been inhabited by a dolichoccephalic race, different from the brachycephalic Poles of the present day; but from the state of the country in early times and the fact that the people with Lithuanians, have to be found on the plains of the Vistula and the Warta. The purest Polish type exists in the basin of the middle Vistula and in Posen. The Poles extend but little beyond the limits of Russian Poland. In East Prussia they occupy the southern slope of the Baltic swelling (the Mazurs), and extend down the left bank of the lower Vistula to its mouth (the Kaszubes or Kassubians). Westward they stretch down the Warta as far as Birnbaum (100 m. east of Berlin); and in the south they extend along the right bank of the Vistula to the river San in western Galicia. In Russia they constitute, with Jews, Lithuanians, Ruthenians and White Russians, the town population, and are divided into the large cities and counties in several governments west of the Divna and the Drener. According to the localities which they inhabit, the Poles take different names. They are called Wielkopolski on the plains of central Poland, while the name of Maloposanie is reserved for those on the Warta. The name of Lebceznick is given to the inhabitants of the marshes of the Ner, that of Kurpie to those of the Podlasie; Kujawiacy, Szlacy in the Silesia, and Gorale in the Carpathians. The Kaszubes, and especially the Mazurs, may be considered as separate stocks of the Polish family. The Mazurs are distinguished from the Poles by their lower stature, broad shoulders and massive frame, and still more by their national dress, which has nothing of the smartness of that of the southern Poles, and by their ancient customs; they have also a dialect of their own, containing many words now obsolete in Poland, and several grammatical forms bearing witness to Lithuanian influence. They submit without difficulty to German culture, and in Prussia are Lutherans. The language of the Kaszubes can also be considered as a separate dialect. The Poles proper are on the whole of medium stature (5 ft. 4-6 in.), finely built, dark in the south and fair in the north, richly endowed by nature, inclined to deeds of heroism, but perhaps deficient in that energy which characterizes the northern races of Europe, and in that sense of unity which has been the strength of their present rulers.

The German element is annually increasing both in number and in influence. In the Lithuanian and Masurian district of the Kalining- ham, is becoming more German than Polish; and throughout the governments west of the Vistula German immigration is going on at a steadily increasing rate, especially in the governments of Plock, Kalisz and Inowrocław. The Jews, who are found everywhere throughout Poland, are nowhere more numerous than in the large towns; many of them are artisans, but in the villages they are almost exclusively engaged as shopkeepers, second-hand dealers, traders on commission, innkeepers and usurers. In the country, both commerce and agriculture are in the hands of their intimately connected trading associations. They contend with Poles on the ground of superiority of their banking burdoril, and "Jew-baiting" is of frequent occurrence. They are increasing much more rapidly than the Slavs.

Agriculture.—From remote antiquity Poland has been celebrated for its great pasturage and fertile soils. Both have been for a long time declining in the 18th century; and towards the beginning of the 19th, the peasants, ruined by their proprietors, or abandoned to the Jews, were in a more wretched condition than even their Russian neighbours. Scarcity of food in the country and subsistence in the cities in 1816 but the peasants received no allotments of land, and the old patrimonial jurisdictions were retained. Compelled to accept the conditions imposed by the landlords and the state, the peasants were seldom able to give compulsory labour in various forms for the use of their land. Only a limited number were considered as permanent farmers, while nearly one-half of them became mere proletaires. Pursuing a policy intended to reconcile the peasants to Russian rule and to break the power of the Polish nobility, the Russian government promulgated, during the outbreak in 1864, a law by which those peasants who were holders of land on estates belonging to private persons, institutions (such as monasteries and the like), or the Crown were recognized as proprietors of the soil—the state paying compensation to the landlords in bonds, and the peasants having to pay a yearly sum to the state for the use of the lands, thus contracted had been cleared off. The valuation of these allotments was more advantageous than in Russia, and the average size of holding amounted to 15 acres per family. Of those who held no land a sum of 1.5 roubles was paid them, and of the whole number of peasant proprietors of land 62,457 were not able to pay this due. These reforms resulted in a temporary increase of prosperity, or at any rate an alleviation of the previous misery of the peasants. But whereas between 1864 and 1873 the prosperity of land purchased was addition to the land granted to them by the government, 297,000 acres, in the period 1873-1893, they bought 640,000 acres and between 1893 and 1905 as much as 1,620,000 acres. Thus the process of breaking up the larger estates is pro- cessed by the government and by the landlords, the former being encouraged to incite farmers to purchase land, and the latter by the law of 1873 the area of cultivated soil increased by 1,350,000 acres, while during the fourteen years 1845-1859 its increase has been only 150,000 acres. But the farmers are met by three difficulties: the lack of pasture-land, the lack of money for improvements, and the very rapid increase in the price of land, all helped to counteract the benefits of the agrarian measures of 1864.

Agriculture in Poland is on the whole carried on according to more advanced methods than in Russia. The extensive cultivation of beetroot, of potatoes for distilleries, and of fodder crops has led to the introduction of a rotation of several years instead of the former "three-fields" system; and agricultural machinery is in more general use, especially on the larger estates of the west. Winter wheat is cultivated on a larger scale than in Russia, although the crop of winter rye (mizit) and winter wheat (k LIABILITY) having a wide repute. Of the land in the possession of the peasants no less than 70% is under crops, and of the land in the larger estates 53%; of the former category 11% and of the latter nearly 50%, the government of Russian Poland, or almost one-half of the total area, are under crops, principally rye, oats, wheat, barley, potatoes and hay, with some flax, hemp, peas, buckwheat and hops. After local wants are supplied, there remains every year a surplus of about 33 million quarters of cereals for export. Beetroot is largely grown for the manufacture of sugar. Potatoes are extensively grown for use in the manufacture of starch. Tobacco, especially of the Welcher type, is grown, especially in the governments of Warsaw, Plock and Lublin. The breeding of livestock (cattle, sheep and horses), is an important source of income. Fine breeds of horses and cattle are kept on the estates, and the smaller farmers have small flocks of sheep and hogs. Bee-keeping is widely followed, especially in the south. Fishing is carried on remuneratively, more particularly on the Vistula and its tributaries.
greatest progress being the textile. Whereas in 1864 the annual production of all factories in Poland was valued at not more than 5,000,000 florins, in 1875, when the factories numbered 21,000, the output was estimated at even less; but in 1905 the value of the industrial production reached 53 millions sterling. The principal industrial centres are Lodz (textiles), Warsaw (sugar, leather and machinery), and Plock (5m. of Dombrowski (mining). The sugar factories and refineries, situated chiefly in the governments of Warsaw, Lublin, and Plock, turn out approximately one million tons of sugar in the year, the Polish sugar industry being exceeding in efficiency by that of the cotton. The cotton, hemp, jute, and woolen manufactures, have been abolished, and the production of engines, machinery, and pottery, has been regulated. The production of flour, beer, and bread is carried on by the numerous distilleries, breweries, potteries, vinegars, chocolate, varnish, furnishing, clothing and brickworks. The cottage industries, such as pottery and basket-making, formerly of considerable importance, are gradually being replaced by the factory system of working.

Southern Poland possesses abundant minerals, especially in the Kielce mountains and the region adjacent to Prussian Silesia. The Devonian sandstones contain malachite ores near Kielce, and copper has been employed since the 17th century. The silver of Kielce and Olkuszy is still found in the Kielce district. The deposits of coal, iron, and copper have been extensively worked since the first half of the 19th century. The iron deposits have been worked up to the present day.

Communications.—The railways of Poland have an aggregate length of 1,300 m. A line of great importance, connecting Vienna with St Petersburg, crosses the country from south-west to north-east through the middle of the country and through Warsaw, and sending a short branch to Lodz. Another important line, connecting Danzig with Odessa, crosses Poland from north-west to south-east. A branch line, parallel to this last, connects Skierniewice with Cracow, and Kielce with the fortress of Warsaw and Ivanгород with Breit-Litovk, by Siedlecké and Lukow. The line from Berlin to St Petersburg traverses the north of Suwalki for 54 m. between Eydtkunen and Kovno.

The trade in walnut is merged with the trade of Russia, under which heading it is treated. With the extension of the railways the fairs have lost much of their importance, but their aggregate yearly returns are still estimated at £3,000,000. The principal fairs are held at Warsaw (quadrifoglio boxes), Leczyna in Kalisz, Skarszewy in Radom, Ciechanowice in Lomza, and Lovicz in Warsaw.

Administration.—The entire administration of Poland is under the governor-general residing at Warsaw. He is at the same time head of the military forces of the "Warsaw military district." Justice in the ordinary courts is administered by the gminas (municipalities), which correspond to those of the mir in Russia; the justices of the peace (nominated by government); the syead, or "court," of the justices of the peace; the district tribunals (asessy) in each government; and the Warsaw courts of appeal and cassation. Poland has had no separate budget since 1867; its income and expenditure are included in those of the empire.

After the insurrection of 1863 all towns with less than 2000 inhabitants were deprived of their municipal rights, and were included, under the designation of possads, in the gminas. Viewed with suspicion by the Russian government, the Polish towns were deprived of self-government like the villages. The elective municipal councils have now enjoyed, in reality, large rights, including that of maintaining their own police; although in reality they were under the rule of the nobility, were practically abolished, and Russian officials were nominated in their place and entrusted with all their rights. The municipal councils were, however, maintained to carry out the orders of the military chiefs. The new municipal law of 1870, first introduced at Warsaw, reduced the functions of the municipal council almost to nothing. The burgomaster is entirely dependent upon the police and the chief of the district, and has to discharge all sorts of functions (bailiff, policeman, &c.) which have nothing to do with municipal affairs. In all official communications the municipal authorities are obliterated, and a gradual elimination of Poles from the administration has been so far accomplished.

Defence.—Poland contains the first line of defence of the Russian empire on its western frontier. The marshy lowlands, covered with forests on the western bank of the Vistula, are a natural defence against an army advancing from the west, and they are strengthened by numerous fortresses and military roads. There are two lines of fortresses between Warsaw and the Bug, with Novogrock, formerly Modlin, in the north, at the mouth of the Bug, and Ivanгород, formerly Demblin, in the south, at the mouth of the Warth. Novogrock is a strongly fortified camp which requires a garrison of 12,000 men and may shelter an army of 50,000 men. The town of Sierock, at the confluence of the Bug and the Narew, is fortified to protect the rear of Novogrock. The Vistula line of fortresses, however, under the great disadvantage of being easily turned from the rear, is not considered as equal to the fortresses in East Prussia or Galicia. Brest-Litovsk, at the western issue from the marches of the Przemy, the towns of Dubno, Lubuk and Bobr, are the last defence to the empire. One diocese (Podlasie) was abolished, and a new one established at Kielce, while several bishops were suppressed. The country is now divided into four dioceses—Warsaw, Sedomierz, Lublin, and Plock.

The educational institutions of Poland are represented by a number of schools in Warsaw, with 1500 students. Teaching has been carried on in Russia since 1863. There are excellent technical schools, an institute of agriculture and forestry at Nowa-Alexandria, and several seminaries for teachers. At Warsaw there is a good observatory, and the Jewish children are mostly sent to the Jewish schools, but there is a sound educational system. Although there has been a decided increase in the number of both the primary and the secondary schools, nevertheless the school accommodation has in neither case kept pace with the growth of the population. The proportion of primary schools has in fact been steadily decreasing, and the applications for admission to the secondary schools and colleges are on the average twice as great as the number of schools. The secondary schools are treated favourably with Russia in the general level of education, for whereas those able to read and write in 1897 amounted in Poland to 20.5% of the population (only 9.3% in 1862), in Russia it was 19.8%.

POLARITY (Lat. polaris, polus, pole), having two poles or parts at which certain properties are the opposite to one another, as in a magnet the ends of which have opposite magnetic characters. The act of producing polarity is termed polarization. For electrolytic polarization see Battery and Electrolysis, and for optical see Polarization of Light below.

POLARIZATION OF LIGHT. A stream of light coming directly from a natural source has no relation to space except that concerned in its direction of propagation, round which its properties are alike on all sides. That this is not a necessary characteristic of light was discovered by Christian Huygens, who showed that, whereas a stream of sunlight in traversing a rhomb of such a size as to enclose one of its acute angles, each of the two emergent streams is divided by a second rhomb into two portions having a relative intensity dependent upon the position with respect to one another of the principal planes of the faces of entry into the rhomb—the planes through the axes of the crystals perpendicular to the refracting surfaces. In certain cases, indeed, one portion vanishes entirely: thus a stream simultaneously refracted in the first rhomb gives an ordinary or an extraordinary stream alone in the second, according as the principal planes are parallel or perpendicular, the reverse being the case with the extraordinary stream of the first rhomb. In intermediate cases the intensities of the two beams are proportional to the squares of the cosines of the angles that the principal plane of the second rhomb makes with the positions in which they have the greatest intensity.
Polarization of Light

On the other hand, if the emergent streams overlap and the common part be examined, it is found to have all the properties of common light. To this phenomenon E. T. Malus gave the name of polarization, as he attributed it, on the emission theory of light, to a kind of polarity of the light-corpuscles. This term has been retained and the ordinary stream is said to be plane polarized in the principal plane of the face of entry into the rhomb, and the extraordinary stream to be plane polarized in the perpendicular plane.

The phenomenon of polarization observed by Huygens remained an isolated fact for over a century, until Malus in 1808 discovered that polarization can be produced independently of double refraction, and must consequently be something closely connected with the nature of light itself. Examining the light reflected from the windows of the Luxembourg palace with a doubly refracting prism, he was led to infer (though more refined experiments have shown that this is not strictly the case) that light reflected at a certain angle, called the polarizing angle, from the surface of transparent substances has the same properties with respect to the plane of incidence as those of the ordinary stream in Iceland spar with respect to the principal plane of the crystal. Thus in accordance with the definition, it is polarized in the plane of incidence. Further, if polarized light fall at the polarizing angle on a reflecting surface, the intensity of the reflected stream depends upon the azimuth of the plane of incidence, being proportional to the square of the cosine of the angle between this plane and the plane of the polarization. At angles other than the polarizing angle common light gives a reflected stream that behaves as a mixture of common light with light polarized in the plane of incidence, and is accordingly said to be partially polarized in that plane. The refracted light, whatever be the angle of incidence, is found to be partially polarized in a plane perpendicular to the plane of incidence, and D. F. J. Arago showed that at all angles of incidence the reflected and refracted streams contain equal quantities of polarized light. The polarizing angle varies from one transparent substance to another, and Sir David Brewster in 1815 enunciated the law that the tangent of the polarizing angle is equal to the refractive index of the substance. It follows then that if a stream of light be incident at the polarizing angle on a pile of parallel transparent plates of the same nature, each surface in turn will be met by the light at the polarizing angle and will give rise to a reflected portion polarized in the plane of incidence. Hence the total reflected light will be polarized in this plane and will of necessity have a greater intensity than that produced by a single surface. The polarization of the light transmitted by the pile is never complete, but tends to become more nearly so as the number of the plates is increased and at the same time the angle of incidence for which the polarization is a maximum approaches indefinitely the polarizing angle (Sir G. G. Stokes, Math. and Phys. Papers, 1v. 145).

In order to isolate a polarized pencil of rays with a rhomb of Iceland spar, it is necessary to have a crystal of such a thickness that the emergent streams are separated, so that one may be stopped by a screen. There are, however, certain crystals that do not possess this thickness, and it is found that a light that is more or less completely polarized. The polarizing action of such crystals is due to the unequal absorption that they exert on polarized streams. Thus a plate of tourmaline of from 1 mm. to 2 mm. in thickness with its faces perpendicular to the optic axis is nearly opaque to light falling normally upon it, and a plate of this thickness parallel to the axis permits of the passage of a single stream polarized in a plane perpendicular to the principal section. Such a plate acts in the same way on polarized light, stopping it or allowing it to pass, according as the plane of polarization is parallel or perpendicular to the principal section. Certain artificial salts, e.g. iodide-sulphate of quinizarin and of pentaerythritol, are similar substances.

From the above instances we see that an instrumental appliance that polarizes a beam of light may be used as a means of detecting and examining polarization. This latter process is termed 'analysis,' and an instrument is called a polarizer or an analyser according as it is used for the first or the second of these purposes.

In addition to the above facts of polarization mention may be made of the partial polarization, in a plane perpendicular to that of emission, of the light emitted in an oblique direction from a white-hot solid, and of the polarization produced by diffraction. Experiments with gratings have been instituted by Sir G. G. Stokes, C. H. A. Holzmann, F. Eisenlohr and others, with the view of determining the direction of the vibrations in polarized light (side infra), but the results have not been consistent, and H. Fizeau and G. H. Quincke have shown that they depend upon the size and form of the apertures and upon the state of the surface on which they are traced. The polarization of the light reflected from a glass grating has also been investigated by I. Fröhlich, while L. G. Gouy has studied the more simple case of diffraction at a straight edge. The polarization of the light scattered by small particles has been examined by G. Goï, J. Tyndall, L. Sorèt and A. Lallemand, and in the case of ultra-microscopic particles by H. Seldentopf and R. Zsigmondy (Drude Ann. 1903, 1.)

An important addition to the knowledge of polarization was made in 1816 by Augustin J. Fresnel and D. F. J. Arago, who summed up the results of a searching series of experiments in the following laws of the interference of polarized light:

1. Under the same conditions in which two streams of common light interfere, two streams of polarized light at right angles are without mutual influence.
2. Two streams polarized in parallel planes give the same phenomena of interference as common light.
3. Two streams polarized at right angles and coming from a stream of common light can be brought to the same plane of polarization without thereby acquiring the faculty of interfering.
4. Two streams polarized at right angles and coming from a stream of polarized light interfere as common light, when brought to the same plane of polarization.

In calculating the conditions of interference in the last case, it is necessary to add a half wave-length to the actual difference of path of the streams, unless the primitive and final planes of polarization lie in the same angle that is related to the vector of the perpendicular planes.

The lateral characteristics of a polarized stream lead at once to the conclusion that the stream may be represented by a vector, and since this vector must indicate the direction in which the light travels as well as the plane of polarization, it is natural to infer that it is transverse to the direction of propagation.

That this is actually the case is proved by experiments on the interference of polarized light, from which it may be deduced that the polarization-vector of a train of plane waves of plane polarized light executes rectilinear vibrations in the plane of the waves. By symmetry the polarization-vector must be either parallel or perpendicular to the plane of incidence: which of these directions is assumed depends upon the character of the incident light.

The general expressions for the rectangular components of a vector transverse to the direction of propagation (a) In the case of waves of length $\lambda$ travelling with speed $v$ are:

$$u = a \cos \left( T - \alpha \right)$$
$$v = b \cos \left( T - \beta \right)$$

where $T = \pi \vartheta (\vartheta - 2\varpi)/\lambda$. The path of the extremity of the vector is then in general an ellipse, traversed in a right-handed direction to an observer receiving the light when the angle $\alpha - \beta$ is between $\varpi$ and $\pi$. It is in a left-handed direction if this angle be between $\pi$ and $2\pi$, or between $\varpi$ and $-\pi$. In conformity with the form of the path, the light is said to be elliptically polarized, right- or left-handedly as the case may be, and the axes of the elliptic path are determined by the planes of
maximum and minimum polarization of the light. In the particular case in which \(a = b\) and \(a - \beta = (2\pi + 1)\pi/2\), the vibrations are circular and the light is said to be circularly polarized.

These different types of polarization may be obtained from a plane polarized beam by passing it through a quarter-wave plate, i.e. a crystalline plate of such a thickness that it introduces a relative retardation of a quarter of a wave between the component streams within it. Such plates are generally made of mica or selenium, and the normal to the plane of polarization of the most retarded stream is called "the axis of the plate." If this axis be parallel or perpendicular to the primitive plane of polarization, the emergent beam remains plane polarized; it is circularly polarized if the axis be at 45° to the plane of polarization, and in other cases it is elliptically polarized with the axes of the elliptic path parallel and perpendicular to the axis of the plate. Conversely a quarter-wave plate may be employed for reducing a circularly or elliptically polarized beam to a state of plane polarization.

Two streams are said to be oppositely polarized when the one is the mirror image of the other with respect to its polarization, what the other becomes when it is turned through an azimuth of \(90^\circ\) and has its character reversed as regards right and left hand. An analytical investigation of the conditions of interference of polarized streams is made in the general theory of interference and the conditions for complete interference, whatever their relative retardation may be, is found to be that the difference of intensity of the streams admits (Sir G. G. Stokes, Math. and Phys. Papers, iii. 233).

It remains to consider the constitution of common unpolarized light. Since a beam of common light can be resolved into plane polarized streams, these on recombination give a stream with properties indistinguishable from those of common light, whatever their relative retardation may be, it is natural to assume that an analytical representation of common light can be obtained in which no longitudinal vector occurs. On the other hand a stream of strictly monochromatic light with a polarization-vector that is entirely transversal must be (in general elliptically) polarized. Consequendy it follows that common light cannot be absolutely monochromatic. The conditions that are necessary in order that a stream of light may behave as natural light have been investigated by Sir G. Gabriel Stokes (loc. cit.), and by E. Verdet (Oeuvres, i. 235), and it may be shown that two polarized streams of a definite character are analytically equivalent to common light provided that they are of equal intensity and oppositely polarized and that there is no common phase relation between the corresponding monochromatic constituents. Further a stream of light of the most general character is equivalent to the admixture of common and polarized light, the polarization being elliptical, circular or plane.

We see then that there are seven possible types of light: common light, polarized light and partially polarized light; the polarization in the latter two cases being elliptical, circular or plane. In common light, the light is the result of two circularly polarized light all have the characteristic of giving two streams of equal intensity on passing through a rhomb of Iceland spar, however it may be turned. They may, however, be distinguished by the fact that on previous transmission through a quarter-wave plate this property is retained in the case of common light, while with the two other types the relative intensity of the streams depends upon the orientation of the rhomb, and with circularly polarized light one stream may be made to vanish. Plane polarized light gives in general two streams of unequal intensity when examined with a rhomb, and for certain positions of the crystal there is only one emergent stream. Circularly polarized, partially elliptically polarized and partially plane polarized light give with Iceland spar two streams of, in general, unequal intensity, neither of which can be made to vanish. They may be differentiated by first passing the light through a quarter-wave plate with its axis parallel or perpendicular to the plane of maximum polarization: for elliptically polarized light thereby becomes plane polarized and one of the streams is extinguished on rotating the rhomb; but with the other two kinds of light this is not the case, and the light is partially plane or partially elliptically polarized according as the plane of maximum polarization remains the same or is changed.

Colour of Crystalline Plates.—It was known to E. T. Malus that the superposition of a doubly refracting plate between two equal and an analyser regulated for extinction has the effect of partially restoring the light, and he used this property to discover double refraction in cases in which the separation of the two refracted ordinary planes was too slight to be detected by the eye. J. Arago in 1811 found that in the case of white light and with moderately thin plates the transmitted light is no longer white but coloured, a variation of brightness but not of tint being produced when the analyser is turned in a certain position. This effect is due to the rotation of the analyser alone producing a change of colour, which passes through white into the complementary tint. This phenomenon was subjected to a detailed investigation by Jean Baptiste Biot during the years 1812 to 1814, and from the results of his experiments Thomas Young, with his brilliant acumen, was led to infer that the colours were to be attributed to interference between different polarized rays of light that had passed through the plate of crystal. This explanation is incomplete, as it leaves out of account the action of the polarizer and analyser, and it was with the purpose of removing this defect that Fresnel and Arago undertook the investigations which have been already cited above and which were the basis of Young's explanation. In Biot's earlier experiments the beam of light employed was nearly parallel; the phenomena of rings and brushes, as seen with a conical pencil of light were discovered by Sir David Brewster in the case of uniaxal crystals in 1815 and in that of biaxal crystals in 1815.

Let \(a, \beta, \gamma\) be the angles that the primitive and final planes of polarization make with the plane of incidence. The polarization of the beam of light is changed as it passes through the plate with a fixed plane, and let \(p\) be the relative retardation of phase of the two streams on emergence from the plate for light of period \(r\). On entry into the crystal the original polarized state is resolved into components represented by the equation of light.

\[ a \cos(\psi - \alpha) \cos T \sin \phi + \sin \cos \phi = B(\psi - \alpha) \cos T \sin \phi \]

and on emergence we may take as the expression of the waves

\[ a \cos \psi \cos T \sin \phi \]

Finally after traversing the analyser the sum of the two resolved components is

\[ a \cos(\psi - \alpha) \cos (\psi - \beta) \cos T \sin \phi \sin \psi(\beta - T) \cos T \sin \phi \]

of which the intensity is

\[ a \cos(\psi - \alpha) \cos (\psi - \beta) \cos T \sin \phi \sin \psi(\beta - T) \cos T \sin \phi \]

\[ a \cos(\psi - \alpha) \sin^2 \sin(\psi - \beta) \cos T \sin \phi \sin \psi(\beta - T) \cos T \sin \phi \]

When the primitive light is white, this expression must be summed for the different monochromatic constituents. In strictness the angle \(\psi\) must be determined for the different constituents on the assumption that it is independent of the plane of polarization, but in the case of white light it is sufficient to employ the mean value of the angle. It is found that with this hypothesis the formula given above is a convenient approximation, and that the field is not appreciably altered by the introduction of a circular plate between the polarizer and analyser. The effect of the circular plate shows no colour when it is very thin, and also when its thickness exceeds a moderate amount. In the former case the retardation of phase of mean period \(r\) is nearly the same for all colours; in the latter the rate of change of retardation is so small that for a small change in the period the intensity passes from a maximum or a minimum, and consequently so many constituents of the light these are so small that for a small change in frequency, that the light presents to the eye the appearance of being white. The true character of the light in this case may be revealed by illuminating it with white light, and by placing between the polarizer and analyser the thin plate of another plate as the planes of polarization of the quicker waves within them are parallel or crossed. In this way a delicate test for slight traces of double refraction is obtained. When the retardation of phase of light of mean period \(r\) is small or a multiple of \(\pi\) a crystalline plate placed between a crossed polarizer and analyser...
exhibits in white light a distinctive greyish violet colour, known as a sedimentation colour, that is peculiar to this plane. With light of high intensity, when the retardation is very slightly increased or diminished, if then the sensitive plate be cut in half and the two parts be placed side by side after the one has been turned through 90° in its own plane, the tint of one half will be an intense grey and that of the other will be lowered when the compound plate is associated with a second doubly refracting plate.

When light from an extended source is made to converge upon the faces of a plane perpendicular to the optic axes, the fringes are obtained. The exact calculation of the intensity in this case is very complicated, and the resulting expression is too unwieldy to be of any use, but as an approximation the formula for the case of a parallel beam of light will be given. The retardation is circular, and the light is therefore being regarded as functions of the angle and plane of incidence and consequently as variables. In monochromatic light, then, the phase retardation of the system is given by the expression

\[ \Delta = \frac{2\pi n d}{\lambda} \]

where \( d \) is the thickness of the plate, \( n \) is the refractive index of the plate at the wavelength \( \lambda \) of the light, and \( \Delta \) is the total path difference. The values of the retardation \( \Delta \) for the principal planes of the plate will be given by the formula

\[ \Delta = \frac{2\pi n d}{\lambda} \cos \theta \]

where \( \theta \) is the angle of incidence.

The plane of polarization can be regarded as corresponding to the plane of the polarizer, and its plane of incidence as the plane of the crystal, the two planes being parallel. The plane of polarization of the light emerging from the retarder will be perpendicular to the plane of incidence, and the plane of incidence will be perpendicular to the plane of the crystal. The plane of polarization of the light emerging from the retarder will be perpendicular to the plane of the crystal, and the plane of incidence will be perpendicular to the plane of polarization.

The phenomenon of interference produced by crystalline plates is of the highest importance, and is the subject of much investigation and experiment. It can be produced by polarized or by the interposition of a quarter-wave between the crystal and the polarizer or analyser. Thus in the two cases described above the brushes disappear and the rings are continuous about their peripheries. In the most important case, on account of its practical application to determining the sign of a crystal, is that in which the plane is light polarized and circularly analysed or the reverse. Let us suppose that the plane of polarization is circular, and that the rings are continuous about their peripheries. Then the plane of polarization of the light is at right angles to the plane of the crystal and at right angles to the plane of the polarizer or analyser. Thus in the two cases described above the brushes disappear and the rings are continuous about their peripheries. In the most important case, on account of its practical application to determining the sign of a crystal, is that in which the plane is light polarized and circularly analysed or the reverse. Let us suppose that the plane of polarization is circular, and that the rings are continuous about their peripheries. Then the plane of polarization of the light is at right angles to the plane of the crystal and at right angles to the plane of the polarizer or analyser.
POLARIZATION OF LIGHT

in the crystalline arrangement of the molecules, as it is lost on fusion or solution, and in several cases belongs to enantiomorphous crystals, the optically active forms being left-handers and the other right-handed optically as well as crystallographically, this being necessarily the case if the property be retained when the crystal is fused or dissolved. In organic bodies the rotary property, as obtained by the researches of T. A. Le Bel [6], and by the observation of P. Hermann and F. Hermans [5], iv. 149] has shown that the results deduced from Airy's waves of permanent type may be obtained by regarding the action of the medium as the superposition of the effects of ordinary double refraction and of the rotary power. As regards the course of the streams on refraction into the crystal, it is found that it is determined by the Huygenian law (see Refraction, § Double); as, however, the two streams in the direction of the axis have different speeds, the rotation of an equal right- and left-hand ray is reversed. This is the principal reason why, on entering a pair of crossed polars, the energy of the light is partly absorbed, and that this is small in thin crystals.
the square of the amplitude of the incident vibrations is equal to the
sum of the squares of the amplitudes of the reflected and refracted
vibrations. Fresnel obtained his formulae by assuming that the optical differ-
ence of media is due to a change in the effective density of the ether,
the medium, and that the change is inconsistent with his theory of
double refraction—and was led to the result that the vibrations
are perpendicular to the plane of polarization. Franz Neugebauer
(Geschichte d. Phys., p. 125) has shown that Fresnel's formulae for
rotation of constant density and different elasticities, arrived at the same
formulae for the intensities of the reflected light polarized in the
principal azimuths, but in this case the vibrations must be regarded
as vorticities normal to the plane of polarization. A comparison of these
views has led to a large number of experimental investigations,
insisted with the idea of deciding between them. In the main
such investigations have only an academic interest, as, whatever the
theory may be, we have to deal with two vectors that are parallel and perpendicular respectively to the plane of polariza-
tion. Thus certain experiments of Otto H. Wiener (Wied. Ann.,
1890, xl. 203) show that chemical action is to be referred to the
latter, and that the hypothesis is only to be decided when we know if it be the mean
kinetic energy or the mean potential energy that determines chemical
action. Similarly on the electromagnetic theory the electric or the
magnetic force will be perpendicular to the plane of polarization,
according as chemical action depends upon the electric or the mag-
netic force. Lord Rayleigh (Scientific Papers, i. 104) has, however,
shewn that Fresnel himself was aware of the limitations of his
view. Fresnel's explanation on the elastic solid theory by Fresnel's hypothesis of a
different density, and from the study of Hertzian oscillations, in
which the direction of the electric vibrations can be a priori assigned,
we are able to obtain an electric result being a phase difference in
reflection at a certain angle, so that the electric force is perpendicular
to the plane of polarization.

It has been supposed in the above that the medium into which
the light enters at the reflecting-surface is the more refracting.
In the contrary case, total reflection commences as soon as sin
= μ = μ, μ being still the relative refractive index of the more highly refracting medium and for greater angles of incidence μ becomes imaginary. Now Fresnel's formulae were obtained by assuming that the incident, reflected and refracted vibrations are in the same or opposite phases at the interface of the media, and since there is no real factor that could convert a sine into a cosine, we have to deal with two vectors that are parallel and perpendicular respectively to the plane of polariza-
tion. This has been confirmed by observations with metallic prisms of small refracting angle. He further showed that except in the cases of copper, lead and gold the dispersion is abnormal—the index of the light in these metals increases with the angle of incidence, so that the co-efficient of extinction for light of a given period, the more copious will be the reflection of that constituent of a mixed pencil. This result has been employed for the purpose of determining the wave
length, and in this way waves of length 0.061 mm, have been isolated by
five successive reflections from the surface of sylvite.

The Study of Polarization.—The best method of obtaining a strong
beam of polarized light is to isolate one of the streams into which
a beam of common light is resolved by double refraction. This
is effected in polarizing prisms of the earlier type, devised by A. M. de
Rochon, H. H. de Sénarmont and W. H. Wollaston, by blocking off
the non-polarized rays. These prisms may also be obtained by combining two equal crystalline prisms cut differently
with respect to the optic axis—an arrangement that achromatises
more or less completely the pencil that is allowed to pass. In
a second method the prism consists of a thin crystalline plate between
two glass prisms turned in opposite directions by a cement of the same refractive index as the glass. This
prismatic index should be equal to the greatest index of the
plates, and if the first is placed at an angle of ±45° with the optic axis
then should be parallel to its faces and in the normal section of
the prisms, while with an uniaxial plate the optic axis should be in
a plane perpendicular to this normal section. These prisms have
the disadvantage that the optical power is quite small, which makes
an ordinary Nicol's prism, but a difficulty seems to be experienced
in finding a suitable permanent cement.

In an accurate determination of the plane of polarization analy-
sers that act by extinction are not of much practical use, and a
different device has to be employed. Savart's analyser consists of
a Savart's plate (see above) connected to a Nicol's prism, the
plane of the plate and the lens of the analyser being placed in the
planes of the plate: the plane of polarization is determined
by turning the analyser until the bands, ordinarily seen, disappear,
in which case it is parallel to one of the principal planes of the plate.
This is shewn in Fig. 10, in which the two plates are shown in series
as they are sometimes used; when the polarizer and analyser
until both halves are equally dark. These instruments are very
sensitive, but care must be taken to avoid errors caused by
changes in the relative intensities of parts of the source of light—
a precaution that is sometimes overlooked in using polarizers
with these analysers. In J. H. Jellet's and M. A. Cornu's analysers

Polarization of Light
POLAR REGIONS

formed—the one from two parts of a rhomb of spar, the other from the particularities of a Nicol’s prism—the two halves of the field are analysed in slightly different planes; but these, though they have certain advantages, are now seldom employed, partly on account of a difficulty in their construction and partly because their images cannot be seen side by side.

The more usual half-shade analyser is available for light of only one frequency, as it depends upon the action of a half-wave plate, in traversing which the plane of polarization is turned through 90°, the same light as is produced by the prism on one side first and on the other side.

The half-shade analyser is the plate, to which is attached a Nicol’s prism with its principal section inclined at a small angle to that of the plate. The eye must be placed on the edge of the plate, and the two halves of the field will only be equally dark when the principal plane of the plate is parallel to the primitive plane of polarization. Another plan, due to J. H. Poynting, is before analysis to impress unequal rotations upon the same light, by means of a beam of light from a Nicol’s prism, cut perpendicularly to the optic axis, and passing through a plate of quartz, at one, the Nicol’s prism at the other.

Elliptically polarized light is investigated by the reduction of the plane of polarization of a plate, and a determination of the resulting plane of polarization. One method consists in finding directly the elliptic constants of the vibration by means of a two-wave plate and an analyser; but the more usual plan is to measure the angle by which the axis of retardation is rotated in one of the two plates with the aid of a polarimeter.

The observation and measurement of rings in crystals polariscopes are constructed on the following principle. Light from an extended source passes after polarization through a Nicol’s prism, placed on the plate, and is then received in an eyepiece furnished with an analyser. If measurements be required, the plate must have a motion round an axis at right angles to either of the axes of vibration, and the analyser and plate must be adjustable. All the rays through a given point in the first principal focal plane of the anterior system of lenses traverse the plate as a parallel beam and are at the corresponding point of the second focal plane of the posterior system, each in its passage being divided into two by the plate having a given relative retardation.

It is on this latter plane that the eyepiece must be focussed, and so the Nicol’s prism and the system of lenses defined with the object for which the polarioscope is intended, and are given for some of the principal types of instruments in Th. Liebisch’s Physikalische Kristallographie.

The second stage of polarization is the analyser, and there are three principal forms. In Wild’s polariometer, light from a soda flame, rendered parallel by a lens, is polarized by a Nicol’s prism, and after traversing the space in which the active substance is to be set, falls on a Savart’s plate placed in front of an astronomical telescope of low power, that contains in its eyepiece a Nicol’s prism, which with the plate forms a Savart’s analyser. A web in the focal plane of telescope marks the point in the field at which the bands are to be made to disappear; this is done by turning the Nicol’s plate by means of a rack and pinion worked by an arm from the observer’s end of the instrument. The polarizing principle is exhibited by the smallest possible gap in the disk, that has a fixed vernier and determines the positions of the polarizer, for which bands disappear as the point of the field. Laurent’s polarimeter is a half-shade instrument. Savart’s plate is always placed in the eyepiece, and the polarizer a half-wave plate half covered with a half-wave plate of quartz, that is cut parallel to the optic axis and has its principal section inclined at a small angle to the former. The action of the quarter-wave plate, proves that the nicol’s plate must be turned in front of a vernier by means of a rack and pinion. The telescope must be focused on the edge of the quartz plate, and in order that all points of the field may be illuminated by the same part of the sky, the telescope must be so adjusted by the screws, that the telescope is situated at the focus of the eyepiece. The telescope is then placed in the field of view, and the object is imaged by the lens on the diaphragm of the object glass of the telescope. The chief features of Savart’s polarimeter are the half-wave plate and the compensator. The former consists of two semicircular plates of quartz, perpendicular to the optic axes and of opposite rotations, so as to have a common diameter and having such a thickness that each rotates the plane of polarization of mean yellow light through the same multiple of 90°. If then a stream of polarized white light traverses the biquartz, it is possible by an analyser to cut off the mean yellow light from half of the field, the other half will then have the sensitive tint; but a small change in the plane of analysis will give the one half a red and the other half a blue tone. A rotation of the plane of polarization is not, however, possible by an adjustment of the analyser, but by an alteration of the rotation with a compensator. This is made of two plates of quartz, cut normally to the optic axis and of opposite rotations, placed the one in front of the other: the thickness of the one plate is fixed, while that of the other can be varied, as it is formed of two equal prisms that can be moved over one another along their common face. When the plates are of equal thickness, their combined effect is nil, but by adjusting the second, a rotation in the one or the other prism can be produced. Compensators may be also be utilized, and the eye can be given half a spectrum of different colours by the other giving the thickness of the resultant quartz plate. At one end of the instrument is placed a polarizer and the analyser, and at the other a Galilean telescope, that must be focused on the edge of biquartz, having in front of its object-glass the compensator and an analyser that is regulated for producing the sensitive tint, when the plates of the compensator have the same thickness. The sensitivity of the instrument depends upon the exactness of the sensitive tint, when the colour of the two halves of the field are the same, and this is liable to be upset by absorption in the substance under investigation. In order to correct this, the light after analysis is divided by means of a diaphragm, and the sensitive side of the analyser may be more or less restored by cutting off some colour, the same for the whole field, by a Nicol’s prism placed in the eyepiece of the telescope. Solle’s spectrometer, as its name implies, is designed to measure the retardation of the analyser, and, by making it work satisfactorily with active media that have nearly the same rotary dispersion as quartz.

BIBLIOGRAPHY.—A bibliography of the subjects treated in this article, to be found in the corresponding chapters of E. Vedet’s Lecons d’optique physique (1869); this work has been brought to a later date in the German translation by Karl Exner (Braunschweig, 1881); references to later works will be found in T. Walker’s The Analytical Theory of Light (1904). In addition to the above the reader may consult for the general subject of polarization the following treatises: Th. Preston (3rd, ed. by C. J. Joly, London, 1890); Bird’s Elements of Optics (1904); W. Wood, Physical Optics (1905); E. Mascart, Traité d’optique (1890); and for the phenomena exhibited by crystals F. Pockel, Lehrbuch der Kristallographie (1906); Th. Liebisch, Physikalische Kristallographie (1891).

POLAR REGIONS, a general term for the regions about the North or South Pole, otherwise called the Arctic or Antarctic regions. The ancients had no actual knowledge of History of the Polar regions. They had probably heard rumours of the light summer nights and the dark winter days of the northernmost parts; the ancients, about 100 B.C., wrote that the Laestrygons having the short nights and the Cimmerians living in perpetual darkness. By astronomical speculations the Greeks had come to the conclusion that north of the Arctic Circle there must be midnight sun at midsummer and no sun at midwinter. The general view was that the Polar regions, north and south, belonged to the uninhabitable frozen zones; while according to a less scientific notion there was a happy region north of the north wind (Boreas), where the sun was always shining and the Hyperboreans led a peaceful life. The first traveller of history who probably approached the Arctic Circle and reached the land of the midnight sun was a Greek, Pytheas, Pytheas, Pytheas (4th century B.C.), from Marseille, who about 334 B.C. made a voyage of discovery northwards along the west coast of Europe, which is one of the most remarkable in history. He visited England, Scotland, the Scottish isles, and probably also northern Norway, which he called Thule. He moved the limits of the known world from the south coast of England northward to the Arctic Circle. It seems probable that he made two or perhaps several voyages. He also discovered the northern coasts of Germany as far east as Jutland.

We hear of no other voyages towards the Arctic regions before the Irish monk Dicuil, writing about 825, mentions the discovery by Irish monks of a group of small islands (the Irish Islands) and a southern country that he calls Thule, where there was hardly any night at midsummer. It is possible that Ireland and the Faeroes were inhabited by a small Celtic population before the Irish mons
came thither. The fact that Irish monks lived in Iceland before the Norsemen settled there in the end of the 9th century is verified by the Icelandic sagas.

In his translation of Orosius, King Alfred inserts the interesting story of the first known really Arctic voyage, told him by the Norwegian Óttar (Alfred calls him Óthore), who about 870 round the North Cape, sailed eastwards along the Murman coast and discovered the White Sea, where he reached the south coast of the Kola Peninsula and the boundary of the land of the Biarmians (Bearmairs). Óttar told King Alfred that "he chiefly went thither, in addition to the seeing of the country, on account of the walruses."

After Óttar's time the king of Norway took possession of all land as far as the White Sea and the land of the Biarmians, and the native "Finns" had to pay him tribute. Many voyages, mostly of hostile nature but also for trade purposes, were undertaken from Norway to the White Sea, and even kings went as far. It is told of King Eric, called Bloodaxe, who died as king of York in England, that he made such a voyage, and fought with the Biarmians, about 920, and about 965 his son Harold Graafeld defeated the Biarmians and killed many people in a great battle near the river Driva, where Archangel was built later.

After having settled in Iceland in the end of the 9th century, the Norsemen soon discovered Greenland and settled there. The first who is reported to have seen the coast of Greenland was a Norwegian, Gunnbjørn Ulfsson, who on his way to Iceland was storm-driven westwards. He came to some islands, afterwards called Gunnbjørnskier, and saw a coast, but, without exploring the new land, he had evidently continued his way till he reached Iceland. The real discoverer and explorer of Greenland was the Norwegian, Eric the Red, who, with his father had settled in Iceland. As he and his men had there been declared outlaw for having killed several people they had to leave Iceland for three years, and he went westward to find the land which Gunnbjørn was reported to have seen. He explored the west coast of Greenland for three years, probably about 982-985. He then returned to Iceland, and founded the following year a colony in Greenland (g.), and many colonists followed, and two Norse settlements were formed, viz. the Eystrabyggd (i.e. eastern settlement) on the south-eastern part of the Greenland west coast, between Cape Farewell and about 61° N. lat., where Eric the Red had his house, Brattalid, at the Eiríksfjord; and the Vestabyggd (i.e. western settlement) in the region of the present Godthåb district, between 65° and 66° N. lat. The Norse settlers carried on their seal and whale-hunting still farther north along the west coast beyond the Arctic circle, and probably in the region of Disco Bay. A rune stone was found in a cairn in the fjord near Kangerlussuaq, north of Upernavik, showing that Norsemen had been there. The stone probably dates from the 14th century. About 1267 an expedition was sent northwards along the west coast and may possibly have reached some distance north of Upernavik.

The last known communication between the Norse settlements in Greenland and Norway was in 1410, when some Icelanders returned, who four years previously had been storm-driven to Greenland. After that time we possess no reliable information about the fate of these settlements. When Greenland was rediscovered in the 16th century no descendants of the Norse settlers were found. The probability is that having gradually been cut off from all communications with Europe, the remaining settlers who had not returned to the motherland were obliged to adopt the Eskimo mode of life, which in those surroundings was far superior to the European, and by intermarriage they would then soon be absorbed amongst the more numerous natives. There is evidence to show that an expedition was probably sent from Denmark or Norway to Greenland in the latter part of the 15th century (perhaps about 1476) under Pining and Pothorst (by Purchas called "Punns and Pothorse"); and perhaps with Olof Scolvus as pilot. It is probable that this expedition had intercourse with the natives of Greenland, and possibly even reached Labrador, but it is unknown whether any remains of the Norse settlements were found on the Greenland west coast.

It is reported by Adam of Bremen (about 1070) that the Norwegian king Harold Haardraade (in the 11th century) made an expedition into the Arctic Sea (probably northwards) in order to examine how far it extended, but we know nothing more about this voyage.

The Portuguese Gaspar Corte-Real discovered Greenland in 1500. He sailed along its east coast without being able to land on account of the ice. Whether he visited the west coast is uncertain. In 1501 he made a new expedition when he also rediscovered Newfoundland. One of his ships returned home to Lisbon, but he himself and his ship disappeared. His brother went in search of him the following year, but was heard of no more.

Cabot's and Corte-Real's discoveries were followed by the development of the Newfoundland and Labrador fisheries,
POLAR REGIONS

and a whole fleet of English, Portuguese, Basque and Breton fishermen was soon met with in these waters, and they probably went along the Hudson coast as far as Hudson Strait, without having left any report of their discoveries.

It is believed, on good grounds, that expeditions (combined English-Portuguese) were sent out to the newly discovered regions from Bristol in 1501 and 1502. It is unknown what their discoveries were, but they may possibly have sailed along the coast of Labrador.

It is possible that John Cabot's son, Sebastian Cabot, made an Arctic expedition in 1558-1509, in search of a short passage to China towards the north-west, and later, in 1521, King Henry VIII. made an attempt to persuade the merchants of London to support him in sending out an expedition under Sebastian Cabot, to the north-western countries. It is uncertain whether it ever started, but it is certain that it achieved nothing of importance.

John Rut sailed from Plymouth in 1527, in order to seek a passage to China through the Arctic seas towards the north-west, following the suggestion of Robert Thorne of Bristol. He met ice in 59° N. lat. and returned to Newfoundland. Several other expeditions were sent out from various countries towards the north-west and west during this period, but no discoveries of importance are known to have been made in the Arctic regions.

There are rumours that the Portuguese, as early as 1484, under King John II., had sent out an expedition towards Novaya Zemlya in search of a north-east passage to India.

Centurione. The Genoese Paolo Centurione probably proposed to King Henry VIII. of England, in 1525, to make an expedition in search of such a passage to India north of Russia, and there is evidence to show that there had been much talk about an undertaking of this kind in England and at the English court during the following period, as it was hoped that a new market might be found for English merchandise, especially cloth. But it led to nothing until 1553, when Sebastian Cabot was one of the chief promoters. Three ships and 112 men under Sir Hugh Willoughby sailed from Ratcliffe on the 10th (20th) May 1555. Richard Chancellor commanded one of the ships, which was separated from the two others in a gale off northern Norway on the 3rd (13th) August. Willoughby, after having sighted land in various places, probably Koldgue Island, where they landed, the coast near the Pechora river and Kanin Nos, came on the 14th (24th) September to a good harbour on the northern coast of the Kola Peninsula. His one ship being leaky, Willoughby resolved to winter there, but he and all his men perished. Chancellor, after his separation from the two other ships, rounded the North Cape, to which he or his sailing-master, Stephen Borough, gave this name. He reached Vardöhus, and after having waited there in vain for Willoughby, he followed the route of the Norsemen to the White Sea and reached the bay of St. Nicholas, with a monastery of this name, near the mouth of the Dvina river, where Archangel was built later. Chancellor undertook a journey to Moscow, made arrangements for commercial intercourse with Russia, and returned next year with his ship, which was, however, plundered by the Flemings, but he reached London safely with a letter from the tsar. In spite of the disaster of Willoughby and his men this expedition became of fundamental importance for the development of English trade. Chancellor's success and his so-called discovery of the passage to the White Sea, which was well known to the Norwegian traders in that region, proved to people in England the practical utility of such adventures. It led to a charter being granted to the Association of Merchant Adventurers, also called the Muscovy or Russia Company, and gave a fresh impulse to Arctic discovery.

Chancellor undertook a new expedition to the White Sea and Moscow in 1555; on his way home in the following year he was wrecked on the coast of Scotland and perished.

In 1556 Stephen Borough (Burrough), who had served with Chancellor, was sent out by the Muscovy Company in a small pinnace called the "Search-thrift," in order to try to reach the river Ob, of which rumours had been heard. Novaya Zemlya, Vaigach Island, and the Kara Strait leading into the Kara Sea, were explored and discovered by Borough, who kept a careful journal of his voyage. In 1580 the company fitted out two vessels under Arthur Pet and Charles Jackman, with orders to sail eastwards of Russia and Asia to the lands of the emperor of Cathay (China). They penetrated through the Kara Strait into the Kara Sea; they possibly saw the west coast of Yalmal, but met with much ice and were compelled to return. The two ships were separated on the way home, Pet reached London on December 26th in safety; Jackman wintered with his ship in Norway and sailed thence in February, but was never heard of again.

About 1574 the Portuguese probably made an attempt to find the north-west passage under Vasques or Corte-Real. They reached "a great entrance," which may have been Hudson Strait, and they "passed above twenty leagues" into it, "without all impediment of ice," • "but their victualls fayling them, . . . they returned backe agayne with joy."

After the expeditions in search of the north-west passage achieved the success of opening up a profitable trade with Russia, via the White Sea, new life was inspired in the undertakings of England on the sea, at the same time the power of the Hanseatic merchants, called the Easterlings, was much reduced. It was therefore only natural that the plan of seeking a north-west passage to China and India should again come to the front in England, and it was much discussed. It was Sir Martin Frobisher who opened that long series of expeditions all of which for three hundred years were sent from England in search of the north-west passage until the last expedition, which actually accomplished it, sailed from Norway. "Being persuaded of a new and nearer passage to Cataya" (China) towards the north-west, Frobisher "determined and resolved wyth himselfe, to go make full prooue thereof . . . or else never to returne againe, knowing this to be the onely thing of the worlde that was left yet undone, whereby a notable mind might be made famous and fortunate." After having attempted in vain for fifteen years to find support for his enterprise, he at last obtained assistance from Ambrose Dudley, earl of Warwick, and through him the interest of Queen Elizabeth was also secured. The Muscovy Company was now obliged to give a licence for the voyage in 1574, and the necessary money was found by London merchants. Aided especially by Michael Lok, an influential merchant and diligent student of geography, Frobisher sailed, on the 7th (17th) of June 1576, from Deptford with two small vessels of 20 and 25 tons, called the "Gabriel" and "Michael," and a small pinnace of 10 tons; the crews amounted to 35 men all told. On the 8th (18th) of July they lost sight of the pinnace, which was seen no more. On the 11th (21st) of July they sighted a high, rugged land, but could not approach it for ice. This was the east coast of Greenland, but, misled by his charts, Frobisher assumed it to be the fictitious Frisland, which was the fabrication of a Venetian, Niccolo Zeno, who in 1558 published a spurious narrative and map (which he pretended to have found) as the work of an ancestor and his brother in the 14th century. The Zeno map was chiefly fabricated on the basis of a map by the Swede Olaus Magnus of 1537 and the map by the Dane Claudius Clavus of the 15th century. It was accepted at the time as a work of high authority, and its fictitious names and islands continued to appear on subsequent maps for at least a century, and have puzzled both geographers at home and explorers in the field. These islands had also been introduced on the charts of Mercator of 1569 and of Ortelius of 1570, but Frobisher probably never saw them. Evidently frightened by the sight of the great quantities of ice off the Greenland coast, one ship, the "Michael," left him secretly, "and returned home wyth great reprise that he was cast away."

The gallant Frobisher continued his voyage towards the north-west in the "Gabriel" alone, although his mast was sprung, his topmast blown overboard, and his "mizen-mast" had to be cut away in a gale. On the 20th of July (Aug. 8) he sighted high
land which he called Queen Elizabeth's Foreland. This was the southern part of Baffin Land (Resolution Island) in about 62° N. lat. He was stopped by ice, but nearly two weeks later he reached the coast and entered an inlet which he considered to be the strait of the north-west passage, and he gave it his own name (it is now Frobisher Bay on Baffin Land). The land was called "Meta Incognita." Frobisher was not well prepared for going much farther, and after his boat with five men had disappeared he returned home, where, unfortunately, some "gold-finders" in London took it into their heads that a piece of dark heavy stone brought back contained gold ore. This caused great excitement; it was now considered much more important to collect this precious ore than to find the north-west passage, and much larger expeditions were sent out in the two following years. As many as fifteen vessels formed the third expedition of 1578, and it was the intention to form a colony with a hundred men in the gold land, but this scheme was given up. Frobisher came into Hudson Strait, which was at first thought to be Frobisher Strait and therefore called Mistaken Strait. There was an open sea without any land or ice towards the west, and Frobisher was certain that he could sail through to the "Mare del Sur" (Pacific Ocean) and "Kathaya," but his first goal was the "gold mines," and the vessels returned home with full loads of the ore. One of them, a buss (small ship) of Bridgewater, called the "Emmanuel," reported that on her voyage home she had first sighted Friesland on the 8th (18th) of September, but four days later she had sighted another land in the Atlantic and sailed along it till the following day; they reckoned its southern end to be in about 57° N. lat. This land soon found its place on maps and charts south-west of Iceland under the name of Buss Island, and as it was never seen again it was after 1745 called "the sunken land of Buss." The explanation is, mistook by the maps, Frobisher assumed Greenland to be Friesland and the Zeno map and Baffin Land was afterwards assumed to be the east coast of Greenland. When the buss on her way home sighted Greenland in about 62° N., she therefore thought it to be Friesland, but when she four days later again sighted land near Cape Farewell and her dead reckoning probably had carried her about two degrees too far south, she naturally considered this to be a new land, which puzzled geographers and navigators for centuries. Owing to a similar mistake, not by Frobisher, but by later cartographers and especially by Davis, it was afterwards assumed that Frobisher Strait (and also Mistaken Strait) was not in Baffin Land but on the east coast of Greenland, where they remained on the maps till the 18th century.

John Davis, who made the next attempt to discover a north-west passage, was one of the most scientific seamen of that age. He made three voyages in three successive years aided and fitted out by William Sanderson and other merchants. Sailing from Dartmouth on the 7th (17th) of June 1585, with two ships, he sighted on the 20th (30th) of July "the most deformed, rocky and mountainous land that ever we saw." He named it the Land of Desolation, although he understood that he had rediscovered "the shore which in ancient time was called Groenland." It was its east coast. He visited the west coast, where Frobisher had also landed and named it for Friesland. Davis anchored in a place called Gilbert's Sound in 64° 40' N. and had much intercourse with the Eskimo. He then, crossing the strait which bears his name, traced a portion of its western shore southwards from about 66° 40' N. lat. and came into Cumberland Sound, which he thought to be the strait of the north-west passage, but returned home on account of contrary winds. In the second voyage (with four ships) Davis traced the western shore of Davis Strait still farther southwards, and sailed along the coast of Labrador. In the third voyage (with three ships) in 1587 he advanced far up his own strait along the west coast of Greenland in a small leaky pinnace, he "Ellin," and reached a lofty granite island in 72° 41' N. lat., which he named Hope Sanderson. He met with ice in the sea west of this place, but reported that there was not "any yeare towards the north, but a great sea, free, large, very salt and blew, and of an unsearchable depth." By contrary winds, however, he was prevented from sailing in that direction. He sailed into Cumberland Sound, but now found that there was no passage. He also passed on his way southwards the entrance to Frobisher Strait, which he named Lumley Inlet, and Hudson Strait, without understanding the importance of the latter. When Davis came to Labrador, where his two larger ships were to have waited for him, they had sailed to England. The little "Ellin," now struck a broken rock and sprung a leak, which was repaired, and he crossed the Atlantic in this small leaky craft. He still believed in the existence of a passage through Davis Strait, but could find no support for another Arctic voyage. Davis was not the first to discover this strait; it was well-known to the Norsemen. Gaspar Corte-Real had possibly also been there, and Frobisher had during his voyages crossed its southern part every year. The result of Davis's discoveries are shown on the Molynex globe, which is now in the library of the Middle Temple; they are also shown on the "New Map" in Hakluyt's Principal Navigations (1598-1600). When Davis was trying to reconcile his discoveries with the previous ones, especially those of Frobisher, he made fatal mistakes as mentioned above.

As early as 1565, by the intervention of a certain Philip Winterkönig, an exile from Vardöhus in Norway, Dutch merchants formed a settlement in Kola, and in 1578 two Dutch ships anchored in the mouth of the river Dvina, and a Dutch settlement was established where Archangel was built a few years later. The leading man in these undertakings was Olivier Brunel, who is thus the founder of the White Sea trade of the Dutch; he was also their first Arctic navigator. He had travelled both overland and along the coast to Siberia and reached the river Ob; he had also visited Kostin Shar on Novaya Zemlya. He propounded plans for the discovery of the north-east passage to China, and in 1581 he went from Russia to Antwerp to prepare an expedition. He probably started with one ship in 1582, on the first Arctic expedition which left the Netherlands. Little is known of its fate except that it ended unsuccessfully with the wreck of the ship in the shallow Pechora Bay, possibly after a vain attempt to penetrate through the Yugar Strait into the Kara Sea. In 1583 we find Olivier Brunel in Bergen trying to organize a Norwegian undertaking, evidently towards the north-east, but it is uncertain whether it led to anything. From this point onwards, however, England began to see the importance of a northern route to China and India, especially as the routes through the southern seas were jealously guarded by the Spaniards and Portuguese, and after 1584 all trade with Portugal, where the Dutch got Indian goods, was forbidden. By Brunel's efforts their attention had been directed towards the north-east passage, but it was not until 1594 that a new expedition was sent out, one of the promoters being Peter Plancius, the learned cosmographer of Amsterdam. Four ships sailed from Huyssendenen on the 5th (15th) of June 1594. Two of these ships from Amsterdam were under the command of Willem Barents, who sighted Novaya Zemlya, north of the Matowsky Strait. It was here that the ships of Barents and Hay became the first to pass through this strait, which has since that date till the 1st (11th) of August Barents continued perseveringly to seek a way through the ice-floes, and discovered the whole western coast as far as the Great Ice Cape, the latitude of which he, with his admirable accuracy, determined to be 77° N. Having reached the Orange Islands at the north-west extremity, he decided to return. The two other ships under the command of Cornelis Nay had discovered the Yugar Strait, through which they sailed into the Kara Sea on the 1st (11th) of August. They reached the west coast of Yalmlai; being sure that they had passed the mouth of the river Ob, and finding the sea open, they thought they had found a free passage to Japan. Nay, who had commanded home on the 1st (11th) of August. A new expedition was made the following year, 1595, with seven ships under the command of Cornelis Nay, as admiral, and Willem Barents as
chief pilot, but it merely made several unsuccessful attempts to enter the Kara Sea through the Yugar Strait. The third expedition was even more important. Two vessels sailed from Amsterdam on the 10th (20th) of July 1596, under the command of Jacob van Heemskerck and Corneliszoon Rip. Barents accompanied Heemskerck as pilot, and Gerrit de Veer, the historian of the voyage, was on board as mate. The masses of ice in the straits leading to the Sea of Kara, and the impenetrable nature of the pack near Novaya Zemlya, had suggested the advisability of avoiding the land and, by keeping a northerly course, of seeking a passage in the open sea. They sailed northwards, and on the 9th (19th) of June discovered Bear Island. Continuing on the same course they sighted a mountainous snow-covered land in about 80° N. lat., soon afterwards being stopped by the polar pack ice. This important discovery was named Spitsbergen, and was believed to be a part of Greenland. Arriving at Bear Island again on the 3rd of July, Rip parted company, while Heemskerck and Barents proceeded eastward, intending to pass round the northern extremity of Novaya Zemlya. On the 20th of August (Sept. 5) they reached Ice Haven, after rounding the northern extremity of the land. Here they wintered in a house built out of driftwood and planks from the 'tweem decks and the deck-house of the vessel. In the spring they made their way in boats to the Lapland coast; but Barents died during the voyage. This was the first time that an arctic winter was successfully faced. The voyages of Barents stand in the first rank among the polar enterprises of the 16th century. They led to flourishing whale and seal fisheries which long enriched the Netherlands.

The English enterprises were continued by the Muscovy Company, and by associations of patriotic merchants of London; and even the East India Company sent an expedition under Captain Waymouth in 1602 to seek for a passage by the opening seen by Davis, but it had no success.

The best servant of the Muscovy Company in the work of polar discovery was Henry Hudson. His first voyage was undertaken in 1607, when he discovered the most northern known point of the east coast of Greenland in 73° N. named "Hold with Hope," and examined the ice between Greenland and Spitsbergen, probably reaching Hakluyt's Headland in 79° 50′ N. On his way home he discovered the island now called Jan Mayen, which he named "Hudson's Hutches." In his second expedition, during the season of 1608, Hudson examined the edge of the ice between Spitsbergen and Novaya Zemlya. In his third voyage he was employed by the Dutch East India Company; he again approached Novaya Zemlya, but was compelled to return westwards, and he explored the coasts of North America, discovering the Hudson river. In 1610 he entered Hudson Strait, and discovered the great bay which bears and immortalizes his name. He was obliged to winter there, undergoing no small hardships. On his way home his crew mutinied and set him, his little son and some sick men adrift in a boat, and the explorer perished in the seas he had opened up.

The voyages of Hudson led immediately to the Spitsbergen whale fishery. From 1609 to 1612 Jonas Poole made four voyages for the prosecution of this lucrative business, and he was followed by Fotherby, Baffin, Joseph, and Edge. These bold seamen, while in the pursuit of whales, added considerably to the knowledge of the archipelago of islands known under the name of Spitsbergen, and in 1617 Captain Edge discovered an island to the eastward, which he named Wyche's Land.

About the same period the kings of Denmark began to send expeditions for the rediscovery of the lost Greenland colony. In 1605 Christian IV. sent out three ships, under the Englishmen Cunningham and Hall and a Dane named Lindcnow, which reached the western coast of Greenland and had much intercourse with the Eskimo. Other expeditions followed in 1606–1607.

Meanwhile, the merchant adventurers of London continued to push forward the western discovery. Sir Thomas Button, in command of two ships, the "Resolution" and "Discovery," sailed from England in May 1612. He entered Hudson Bay, crossed to the western shore, and made a voyage at the mouth of a river in 58° 30′ N. This river was named Nelson river after the master of the ship, who died and was buried there. Next year Button explored the shore of Southampton Island as far as 65° N., and returned home in the autumn of 1613. An expedition under Captain Gibbons despatched in 1614 to Hudson Bay was a failure; but in 1615 Robert Bylot as master and William Baffin as pilot and navigator in the "Discovery" examined the coasts of Hudson Strait and to the north of Hudson Bay, and Baffin, who was the equal of Davis as a scientific seaman, made many valuable observations. In 1616 Bylot and Baffin again set out in the "Discovery." Sailing up Davis strait they passed that navigator's farthest point at Sanderson's Hope, and sailed round the great channel with smaller channels leading from it which has been known ever since as Baffin Bay. Baffin named the most northern opening Smith Sound, after the first governor of the East India Company, and the munificent promoter of the voyage, Sir Thomas Smith. Lancaster Sound and Jones Sound were named after other promoters and friends of the voyage. The fame of Baffin mainly rests upon the discovery of a great channel extending north from Davis Strait; but it was unjustly dimmed for many years, owing to the omission of Purchas to publish the navigator's tabulated journal and map in his great collection of voyages. It was two hundred years before a new expedition sailed north through Baffin Bay. It may be mentioned, as an illustration of the value of these early voyages to modern science, that Professor Hansteen of Christiania made use of Baffin's magnetic observations in the compilation of his series of magnetic maps. In 1619 Denmark sent out an expedition, under the command of Jens Munk, in search of the north-west passage, with two ships and 64 men. They reached the west coast of Hudson Bay, where they wintered near Churchill river, but all died with the exception of one man, a boy, and Munk himself, who managed to sail home in the smallest ship.

In 1631 two expeditions were despatched, one by the merchants of London, the other by those of Bristol. In the London ship "Charles" Luke Fox explored the western side of Hudson Bay as far as the place called "Sir Thomas Roe's Welcome." In August he encountered Captain James and the Bristol ship "Maria" in the middle of Hudson Bay, and went north until he reached "North-west Fox's farthest," in 66° 47′ N. He then returned home and wrote an entertaining narrative. Captain James had to winter off Charlton Island, in James Bay, the southern extreme of Hudson Bay, and did not return until October 1632. Another English voyager, Captain Wood, attempted, without success, to discover a north-east passage in 1636 through the sea round the North Pole, but was wrecked on the coast of Novaya Zemlya.

Of the 16th and 17th centuries were periods of discovery and daring enterprise. Hudson Strait and Bay, Davis Strait and Baffin Bay, the icy seas from Greenland to Spitsbergen and from Spitsbergen to Novaya Zemlya had all been explored; but much more was not discovered than had been well known to the Norsemen five or six centuries earlier. The following century was rather a period of reaping the results of former efforts than of discovery. It saw the settlement of the Hudson Bay Territory and of Greenland, and the development of the whale and seal fisheries.

The Hudson's Bay Company was incorporated in 1670, and Prince Rupert sent out Zachariah Gillan, who wintered at Resolution Bay. At first very slow progress was made. A voyage undertaken by Mr Knight, nearly 80 years old, who had been appointed governor of the factory at Nelson river, was unfortunate, as his two ships were lost and the crews perished. This was in 1719. In 1722 John Scruggs was sent from Churchill river in search of the missing ships, but merely entered Sir Thomas Roe's Welcome and returned. His reports were believed to offer decisive proofs of the existence
of a passage into the Pacific; and a naval expedition was despatched under the command of Captain Christopher Middleton, consisting of the "Discovery" pink and the "Furnace" bomb. Wintering in Churchill river, Middleton started in July 1742 and discovered Wager river and Repulse Bay. In 1746 Captain W. Moor made another voyage in the same direction, and explored the Wager Inlet. Later in the century the Hudson's Bay Company's servants made some important land journeys to discover the shores of the American polar ocean. From 1769 to 1772 Samuel Hearne descended the Coppermine River to the polar sea; and in 1789 Alexander Mackenzie discovered the mouth of the Mackenzie river. (For the establishment of the modern Danish settlements in Greenland, see Greenland.)

The countrymen of Barents vied with the countrymen of Hudson in the perilous calling which annually brought fleets of ships to the Spitsbergen seas during the 17th and 18th centuries. The Dutch had their large summer station for boiling down blubber at Smeerenburg, near the northern extreme of the west coast of Spitsbergen. Captain Vlaamgh, in 1664, advanced as far round the northern end of Novaya Zemlya as the winter quarters of Barents. In 1700 Captain Wolde sailed by Witen and so far north in the longitude of Novaya Zemlya and to have seen an extent of 40 m. of broken land, but Theunis Ys, one of the most experienced Dutch navigators, believed that no vessel had ever been north of the 82d parallel. In 1671 Frederick Martens, a German surgeon, visited Spitsbergen, and wrote the best account of its physical features and natural history that existed previous to the time of Scoresby. In 1707 Captain Cornelis Giles went far to the eastward along the northern shores of Spitsbergen, and saw land to the east in 80° N., which has since been known as Giles Land. The Dutch geographical knowledge of Spitsbergen was embodied in the famous chart of the Van Keulens (father and son), 1700-1728. The Dutch whale fishery continued to flourish until the French Revolution, and formed a splendid nursery for training the seamen of the Netherlands. From 1700 to 1775 the whaling fleet numbered 100 ships and upwards. In 1710 the Dutch opened a whale fishery in Davis Strait, and continued to frequent the west coast of Greenland for upwards of sixty years from that time. The most flourishing period of the British fishery in the Spitsbergen and Greenland seas was from 1732 to 1820. Bounties of 40s. per ton were granted by act of parliament; and in 1778 as many as 255 sail of whalers were employed. In order to encourage discovery £5000 was offered in 1776 to the first ship that should sail beyond the 89th parallel (16 Geo. III. c. 6). Among the numerous daring and able whaling captains, William Scoresby takes the first rank, alike as a successful whaler and a scientific observer. His admirable 'Account of the Arctic Regions' is still a textbook for all students of the subject. In 1806 he succeeded in advancing his ship "Resolution" as far north as 81° 12' 42". In 1822 he forced his way through the ice which encumbered the approach to land on the east coast of Greenland, and surveyed that coast from 75° down to 69° N., a distance of 400 m. Scoresby combined the closest attention to his business with much valuable scientific work and to insignificant amount of exploration.

The Russians, after the acquisition of Siberia, succeeded in gradually exploring the whole of the northern shores of that vast region. In 1648 a Cossack named Simon Dezhnev is said to have equipped a boat expedition in the river Kolyma, passed through the strait since named after Bering, and reached the Gulf of Anadyr. In 1738 a voyage was made by two Russian officers from Archangel to the mouths of the Ob and the Yenisei. Efforts were then made to effect a passage from the Yenisei to the Lena. In 1733 Lieut. T. P. Chelyuskin, as far as 74° N., near the cape which bears his name; and in 1743 he rounded that most northern point of Siberia in sledges, in 77° 41' N. Captain Vitus Bering, a Dane, was appointed by Peter the Great to command an expedition in 1725. Two vessels were built at Okhotsk, and in July 1728 Bering ascertained the existence of a strait between Asia and America. Bering was again employed. He sailed from Okhotsk in a vessel called the "St Paul," with G. W. Steller on board as naturalist. Their object was to discover the American side of the strait, and they sighted the magnificent peak named by Bering Mt St Elías. The Aleutian Islands were also explored, but the ship was wrecked on an island named after the ill-fated discoverer, and scurvy broke out amongst his crew. Bering himself died there on the 8th of December 1741. Thirty years after the death of Bering a Russian merchant named Liakhoff discovered the New Siberia or Liakhoff Islands, and in 1771 he obtained the exclusive right from the empress Catherine to dig there for fossil ivory. These islands were more fully explored by an officer named Hedenström in 1809, and seekers for fossil ivory annually resorted to them. A Russian expedition under Captain Chitschakoff, sent to Spitsbergen in 1764, was only able to attain a latitude of 80° 30' N.

From 1773 onwards to the end of the 19th century the objects of polar exploration were mainly the acquisition of knowledge in various branches of science. It was on these grounds that Daines Barrington and the Royal Society induced the British government to undertake arctic exploration once more. The result was that two vessels, the "Racehorse" and "Carcass" bombs, were commissioned, under the command of Captain J. C. Phipps. The expedition sailed from the Nore on the 2nd of June 1773, and was stopped by the ice to the north of Håkuyt Headland, the north-western point of Spitsbergen. Phipps reached the Seven Islands and discovered Walden Island; but beyond this point progress was impossible. When they attained their highest latitude in 80° 49' N., north of the central part of the Spitsbergen group, the ice at the edge of the pack was 24 ft. thick. Captain Phipps returned to England in September 1773. Five years afterwards James Cook received instructions to proceed northward from Kamchatka and search for a north-east or north-west passage from the Pacific to the Atlantic. In accordance with these orders Captain Cook, during his third voyage, reached Cape Prince of Wales, the western extremity of America, on the 9th of August 1778. His ships, the "Resolution" and "Discovery," arrived at the edge of the ice, after passing Bering Strait, in 70° 41' N. On the 17th of August the farthest point seen on the American side was named Icy Cape. On the Asiatic side Cook's survey was extended to Cape North. In the following year Captain Clerke, who had succeeded to the command, made another voyage, but his ship was beset in the ice, and so much damaged that further attempts were abandoned.

The wars following the French Revolution put an end to voyages of discovery till, after the peace of 1815, north polar research found a powerful and indefatigable advocate in Sir John Barrow. Through his influence a measure for promoting polar discovery became law in 1818 (35 Geo. III. c. 20), by which a reward of £20,000 was offered for making the northern passage, and of £5000 for reaching 80° N., while the commissioners of longitude were empowered to award proportionate sums to those who might achieve certain portions of such discoveries. In 1817 the icy seas were reported by Captain Scoresby and others to be remarkably open, and this circumstance enabled Barrow to obtain sanction for the despatch of two expeditions, each consisting of two whalers—one to attempt discoveries by way of Spitsbergen and the other by Baffin Bay. The vessels for the Spitsbergen route, the "Dorothea" and "Treat," were commanded by Captain David Buchan and Lieut. John Franklin, and sailed in April 1818. Driven into the pack by the ice, they reached the extreme south, both vessels were severely nippered, and had to retreat to the west. The other expedition, consisting of the "Isabella" and "Alexander," commanded by Captain John Ross and Lieut.
Edward Parry, followed in the wake of Baffin's voyage of 1616. Ross sailed from England in April 1818. The chief merit of his voyage was that it vindicated Baffin's accuracy as a discoverer. Its real result was that he proved that the bay was a sheet of water which continued to be frequented by a fleet of whalers every year. Captain Ross thought that the inlets reported by Baffin were merely bays, while the opinion of his second in command was that a wide opening to the westward existed through the Lancaster Sound of Baffin.

Parry was selected to command a new expedition in the following year. His two vessels, the "Hecla" and "Griper," passed through Lancaster Sound, the continuation of which was named Barrow Strait, and advanced westward, with an archipelago on the right, since named as the Parry Islands. He observed a wide opening to the north, which he named Wellington Channel, and sailed onwards for 300 m. to Melville Island. He was stopped by the impenetrable polar pack of vast thickness which surrounds the archipelago to the north of the American continent, and was obliged to winter in a harbour on the south coast of Melville Island. Parry's hygienic arrangements during the winter were judicious, and the scientific results of his expedition were valuable. The vessels returned in October 1820; and a fresh expedition in the "Fury" and "Hecla," again under the command of Captain Parry, sailed from the Nore on the 8th of May 1821, and passed their first winter on the coast of the newly discovered North Peninsula in 66° 17' N. Still persevering, Parry passed his second winter among the Eskimo at Igloolik in 69° 20' N., and discovered a channel leading westward from the head of Hudson Bay, which he named Fury and Hecla Strait. The expedition returned in the autumn of 1823. Meantime Parry's friend Franklin had been employed in attempts to reach by land the northern shores of America, hitherto only touched at two points by Hearne and Mackenzie. Franklin went out in 1819, with Dr John Richardson, George Back and Robert Hood. They landed at York factory, and proceeded to the Great Slave Lake. In August of the following year they started for the Coppermine river, and, embarking on it, reached its mouth on the 18th of July 1821. From that point 550 m. of coast-line were explored, the extreme point being called Cape Turnagain. Great sufferings, from starvation and cold, had to be endured during the return journey; but eventually Franklin, Richardson and Back arrived safely at Fort Chippewyan.

It was thought desirable that an attempt should be made to connect the Cape Turnagain of Franklin with the discoveries made by Parry during his second voyage; but the first effort, under Captain Lyon in the "Griper," was unsuccessful. In 1824 three combined attempts were organized. While Parry again entered by Lancaster Sound and pushed down a great opening he had seen to the south named Prince Regent Inlet, Captain Beechey was to enter Bering Strait, and Franklin was to make a second journey by land to the shores of Arctic America. Parry was unfortunate, but Beechey entered Bering Strait in the "Blossom" in August 1826, and extended our knowledge as far as Point Barrow in 72° 23' 36" N. lat. Franklin, in 1825-1826, descended the Mackenzie river to its mouth, and explored the coast for 274 m. to the westward; while Dr Richardson discovered the shore between the mouths of the Mackenzie and Coppermine, and sighted land to the northward, named by him Wollaston Land, the dividing channel being called Union and Dolphin Strait. They returned in the autumn of 1826.

Work was also being done in the Spitsbergen and Barents Seas. From 1821 to 1824 the Russian Captain Litke was surveying the west coast of Novaya Zemlya as far as Cape Nassau, and examining the ice of the adjacent sea. In May 1823 the "Griper" sailed, under the command of Captain Clavering, to convey Captain Sabine to the polar regions in order to make pendulum observations. Clavering pushed through the ice in 75° 30' N., and succeeded in reaching the east coast of Greenland, where observations were taken on Pendulum Island. He charted the coast-line from 76° 30' E.

In Parry's attempt to reach the pole from the northern coast of Spitsbergen by means of sledgo-boats (see Parry), the highest latitude reached was 82° 45' N., and the attempt was persevered in until it was found that the ice as a whole was drifting to the south more rapidly than it was possible to travel over it to the north.

In 1829 the Danes undertook an interesting piece of exploration on the east coast of Greenland. Captain Graah of the Danish navy rounded Cape Farewell in boats, with four Europeans and twelve Eskimo. He advanced as far as 65° 18' N. on the east coast, where he was stopped by an insurmountable barrier of ice. He wintered in 65° 22' N., and returned to the settlements on the west side of Greenland in 1830.

In the year 1829 Captain John Ross, with his nephew James Clark Ross, having been furnished with funds by a wealthy distiller named Felix Booth, undertook a private expedition of discovery in a small vessel called the "Victory." Ross proceeded down Prince Regent Inlet to the Gulf of Boothia, and wintered on the eastern side of a land named by him Boothia Felix. In the course of exploring excursions during the summer months James Ross crossed the land and discovered the position of the north magnetic pole on the western side of it, on the 31st of July 1831. He also discovered a land to the westward of Boothia which he named King William Land, and the northern shore of which he examined. The most northern point was called Cape Felix, and thence the coast trended south-west to Victory Point. The Rosses could not get their little vessel out of its winter quarters. They passed three winters there, and then fell back on the shores at Fury Beach, where they passed their fourth winter, 1832-1833. Eventually they were picked up by a whaler in Barrow Strait, and brought home. Great anxiety was naturally felt at their prolonged absence, and in 1833 Sir George Back, with Dr Richard King as a companion, set out by land in search of the missing explorers. Wintering at the Great Slave Lake, they left Fort Reliance on the 7th of June 1834, and descended the Great Fish river for 550 m. The mouth was reached in 65° 11' N., and then the want of supplies obliged them to return.

In 1836 Sir George Back was sent, at the suggestion of the Royal Geographical Society, to proceed to Repulse Bay in his ship, the "Terror," and then to cross an assumed isthmus and examine the coast-line thence to the mouth of the Great Fish river; but the ship was obliged to winter in the drifting pack, and was brought home in a sinking condition.

The tracing of the polar shores of America was completed by the Hudson's Bay Company's servants. In June 1837, Thomas Simpson and P. W. Dease left Chippewyan, reached the mouth of the Mackenzie, and connected that position with Point Barrow, which had been discovered by the "Blossom" in 1826. In 1839 Simpson passed Cape Turnagain of Franklin, tracing the coast eastward so as to connect with Back's work at the mouth of the Great Fish River. He landed at Montreal Island in the mouth of that river, and then advanced eastward as far as Castor and Pollux rivers, his farthest eastern point. On his return he travelled along the north side of the channel, the south shore of the King William Island discovered by James Ross. The south-western point of this island was named Cape Herschel, and there Simpson built a cabin on the 26th of August 1839. Little remained to do in order to complete the delineation of the northern shores of the American continent, and this task was entrusted to Dr John Rae, a Hudson's Bay factor, in 1846. He went in boats to Repulse Bay, where he wintered in a stone hut nearly on the Arctic Circle; and there he and his six Orkney men maintained themselves on the deer they shot. During the spring of 1847 Dr Rae explored on foot the shores of a great gulf having 700 m. of coast-line. He thus connected the work of Parry, at the mouth of Fury and Hecla.
Strait, with the work of Ross on the coast of Boothia, proving that Boothia was part of the American continent.

While British explorers were thus working hard to solve some of the geographical problems relating to Arctic America, the Russians were similarly engaged in Siberia. In 1821

Lieu. F. F. Anjou made a complete survey of the New Siberia Islands, and came to the conclusion that it was not possible to advance far from them in a northerly direction, owing to the thinness of the ice and to open water existing within 20 or 30 m. Baron Wrangel prosecuted similar investigations from the mouth of the Kolyma between 1820 and 1823. He made four journeys with dog sledges, exploring the coast between Cape Chelagaski and the Kolyma, and brought back a quantity of samples from some 200 m. distant from the land, but he was always stopped by thin ice.

In 1843 Middendorf was sent to explore the region which terminates in Cape Chelyuskin. He reached Taimyr Bay in the height of the short summer, whereas he saw open water and no ice blink in any direction. The whole arctic shore of Siberia had now been explored and delineated, but no vessel had yet rounded the extreme northern point.

The success of Sir James Ross’s Antarctic expedition and the completion of the northern coast-line of America by the Hudson’s Bay Company’s servants gave rise in 1845 to a fresh attempt to make the passage from Lancaster Sound to Bering Strait. The story of the unhappy expedition of Sir John Franklin, in the “Erebus” and “Terror,” is told under Franklin; but some geographical details may be given here. The heavy polar ice flows south-east between Melville and Baring Islands, down McClintock Channel, and impinges on the north-west coast of King William Land. It was this branch from the “palaeoecystic” sea which finally stopped the progress of Franklin’s expedition. On leaving the winter quarters at Beechy Island in 1846 Franklin found a channel leading south, along the western shore of the land of North Somerset discovered by Parry in 1819. If he could reach the channel on the American coast, he knew that he would be able to make his way along it to Bering Strait. This channel, now called Peel Sound, pointed directly to the south. He sailed down it towards King William Island, with land on both sides. But directly the southern point of the western land was passed and no longer shielded the channel, the great ice stream from Melville Island, pressing on King William Island, was encountered and found impassable. Progress might have been made by rounding the eastern side of King William Island, but its insularity was then unknown.

It was not until 1848 that a new determination to be felt about the Franklin expedition. In the spring of that year Sir James Ross sailed with two ships, the “Erebus” and “Terror,” under Captain Sir James M’Clintock. They left the “Terror” at Cape Barrow in order to explore the coast, and the “Erebus” next wintered at Leopold Harbour, near the north-east point of North Devon. In the spring he made a long sledge journey with Lieut. Leopold M’Clintock along the northern and western coasts of North Somerset, but found nothing.

On the return of the Ross expedition without any tidings, the country became thoroughly alarmed. An extensive plan of search was organized—the “Enterprise” and “Investigator” under Captain M’Clintock proceeding by Bering Strait, while the “Assistance” and “Resolute,” with two steam tenders, the “Pioneer” and “Intrepid,” sailed on the 3rd of May 1850 to renew the search by Barrow Strait, under Captain Horatio Austin. Two brig, the “Lady Franklin” and “Sophia,” under William Penny, an energetic and able whaling captain, were sent by the same route. He had with him Dr Sutherland, a naturalist, who did much valuable scientific work.

Austin and Penny entered Barrow Strait, and Franklin’s winter quarters of 1845–1846 were discovered at Beechy Island; but there was no record of any kind indicating the direction taken by the ships. Stopped by the ice, Austin’s expedition wintered (1850–1851) in the pack off Griffith Island, and Penny found refuge in a harbour on the south coast of Cornwallis Island. Austin, who had been with Parry during his third voyage, was an admirable organizer. His arrangements for passing the winter were carefully thought out and answered perfectly. In concert with Penny he planned a thorough and extensive system of search by means of sledge-travelling in the spring, and Lieut. M’Clintock superintended every detail of this part of the work with unfailing forethought and skill. Penny undertook the search by Wellington Channel. M’Clintock advanced to Melville Island, marching over 770 m. in eighty-one days; Captain Ommannay and Sheard Osborn pressed southward and discovered Prince of Wales Island. Lieut. Brown examined the western shore of Peel Sound. The search was exhaustive; but, except the winter quarters at Beechy Island, no record was made. The absence of any record made Captain Austin doubt whether Franklin had ever entered Beechy Island; so he also examined the entrance of Jones Sound, the next inlet from Baffin Bay north of Lancaster Sound, on his way home, and returned to England in the autumn of 1851. This was a thoroughly well conducted expedition, especially as regards the sledge-travelling, which M’Clintock brought to great perfection.

So far as the search for Franklin was concerned, nothing remained to be done west or north of Barrow Strait.

In 1851 the “Prince Albert” schooner was sent out by Lady Franklin, under Captain Wm. Kennedy, with Lieut. Bellot of the French navy as second. They wintered on the east coast of North Somerset, and in the spring of 1852 the gallant Frenchman, in the course of a long sledge journey, discovered Bellot Strait, separating North Somerset from Boothia—thus proving that the Boothia coast facing the strait was the northern extremity of the continent of America.

The “Enterprise” and “Investigator” sailed from England in January 1850, but accidentally parted company before they reached Bering Strait. On the 6th of May 1851 the “Enterprise” passed the strait, and rounded Point Barrow on the 29th. Collinson then made his way up the narrow Prince of Wales Strait, between Banks and Prince Albert Islands, and reached Prince Royal Islands, where M’Clure had been the previous year. Returning southwards, the “Enterprise” wintered in a sound in Prince Albert Island in 70° 35’ N. and 117° 35’ W. Three travelling parties were despatched in the spring of 1852—one to trace Prince Albert Land in a southerly direction, while the others explored Prince of Wales Strait, one of them reaching Melville Island. In September 1852 the ship was free, and Collinson pressed eastward along the coast of North America, reaching Cambridge Bay (Sept. 26), where the second winter was passed. In the spring he examined the shores of Victoria Land as far as 70° 30’ N. and 160° 45’ W.; here he was within a few miles of Point Victory, where the fate of the Franklin expedition was discovered. They started for “Enterprise” again put to sea on the 5th of August 1853, and returned westward along the American coast, until she was stopped by ice and obliged to pass a third winter at Camden Bay, in 70° 8’ N. and 145° 20’ W. In 1854 this remarkable voyage was completed, and Captain Collinson brought the “Enterprise” back to England.

Meanwhile M’Clure in the “Investigator” had passed the winter of 1850–1851 at the Princess Royal Islands, only 30 m. from Barrow Strait. In October M’Clure ascended a hill whence he could see the frozen surface of Barrow Strait, which was navigated by Parry in 1819–1820. Thus, like the survivors of Franklin’s crews when they reached Cape Herschel, M’Clure discovered a north-west passage. It was impossible to reach it, for the stream of heavy packed ice which stopped Franklin off King William Land lay athwart their northward course; so, as soon as he was free in 1851, M’Clure turned southwards, round the southern extremity of Banks Land, and commenced to force a passage to the northward between the western shore of that land and the enormous fields of ice which pressed upon it. The cliffs rose like walls on one side, while on the other the stupendous ice of the “palaeoecystic sea” rose from the water to a level with the “Investigator’s” lower yards. After many hairbreadth escapes M’Clure took refuge in a bay on the northern shore of Banks Land, which he named the Bay of...
The drift of the "Resolute" was a remarkable proof of the direction of the current out of Barrow Strait. She was abandoned in 1854, and was saved in the summer months of 1855 by Dr. Kellett's sledge party. The "Resolute" sighted in 67° N. Lat. about twenty miles from Cape Mercy, in Davis Strait. She had drifted nearly a thousand miles, and having been brought into an American port, was purchased by the United States and presented to the British government.

In 1853 Dr. Rae was employed to connect a few points which would complete the examination of the coast of America, and establish the insularity of King William Land. He went up Chesterfield Inlet and the river Quoich, wintering with eight men at Repulse Bay, where a large fish was found. In 1854 he set on a journey which occupied fifty-six days in April and May. He succeeded in connecting the discoveries of Simpson with those of James Ross, and thus established the fact that King William Land was an island. Rae also brought home the first tidings and relics of Franklin's expedition gathered from the Eskimo, which decided the Admiralty to award him the £10,000 offered for definite news of Franklin's fate. Lady Franklin, however, sent out the "Fox" under the command of M'Clintock (see Franklin). M'Clintock prosecuted an exhaustive search over part of the west coast of Boothia, the whole of the shores of King William Land, the mouth of the Great Fish river and Montreal Island, and Allen Young completed the discovery of the southern side of Prince of Wales Island.

The catastrophe of Sir John Franklin's expedition led to 7000 m. of coast-line being discovered, and to a vast extent of unknown country being explored, securing very considerable additions to geographical knowledge.

The American nation was first led to take an interest in Polar research through a noble and generous sympathy for Franklin and his companions. Mr. Grinnell of New York gave practical expression to this feeling. In 1850 he equipped two vessels, the "Advance" and "Rescue," to aid in the search, commanded by Lieuts. de Haven and Grinnell, and accompanied by Dr. E. K. Kane. They reached Beechey Island on the 27th of August 1850, and assisted in the examination of Franklin's winter quarters, but returned without wintering. In 1853 Dr. Kane, in the little brig "Advance," of 120 tons, undertook to lead an American expedition up Smith Sound, the most northern outlet from Baffin Bay. The "Advance" reached Smith Sound on the 7th of August 1853, but was stopped by ice in 78° 45' N. only 17 m. from the entrance. Kane described the coast as consisting of precipitous cliffs 800 to 1200 ft. high, and at their base there was a belt of ice about 18 ft. thick, resting on the beach. Dr. Kane adopted the Danish name of "ice-foot" (is fad) for this permanent frozen ledge. He named the place of his winter quarters Van Rensselaer Harbour. In the spring some interesting work was done. A great glacier was discovered with a sea face 45 m. long and named the Humboldt glacier. Dr. Kane's steward, Morton, crossed the foot of this glacier with a team of dogs, and reached a point of land beyond named Cape Constitution. But sickness and want of means prevented much from being done by travelling parties. Scurvy attacked the whole party during the second winter, although the Eskimo supplied them with fresh meat and were true friends in need. On the 17th of May 1855 Dr. Kane abandoned the brig, and reached the Danish settlement of Upernivik on the 5th of August. Lieut. Hartstene, who was sent out on search for Kane, reached the Van Rensselaer Harbour after he had gone, but took the retrieving crew on board on his return voyage.

On the 10th of July 1860 Dr. J. I. Hayes, who had served with Kane, sailed from Boston for Smith Sound, in the schooner "United States," of 130 tons and a crew of fifteen men. His object was to follow up the line of research opened by Dr. Kane. He wintered at Port Foulke, in 78° 17' N., but achieved nothing of importance, and his narrative is not to be depended on.
Charles Hall (q.v.), in his first journey (1860–1862), discovered remains of a stone house which Sir Martin Frobisher built on the coast of Baffin Island in 1578. In his second expedition (1864–1866) Hall reached the line of the retreat of the Franklin survivors, at Todd's Island and Peffer River, on the south coast of King William Island. He heard the story of the retreat and of the wreck of one of the ships from the Eskimo; he was told that seven bodies were buried at Todd Island; and he brought home some bones which are believed to be those of Lieut. Le Vesconte of the "Erebus." Finally, in 1871 he took the "Polaris" for 250 m. up the channel which leads northwards from Smith Sound. The various parts of this long channel are called Smith Sound, Kane Basin, Kennedy Channel, and Robeson Channel. The "Polaris" was beset in 83° 17' N. latitude on August 15, and after two quarters were in thank God Harbour, 8° 48' N., and here Hall died.

The Spitsbergen seas were explored during last century by Norwegian fishermen as well as by Swedish and German expeditions and by British yachtsmen. In 1827 the Norwegian geologist Keilhau made an expedition to Bear Island and Spitsbergen which was the first purely scientific Arctic expedition. The Norwegian Spitsbergen fishery dates from 1820, but it was only in the latter part of thecentury that Professor Mehn of Christiania carefully collected information from the captains who had taken part in the work when at its height. In 1863 Captain Carlsen circumnavigated the Spitsbergen group for the first time in a brig called the "Jan Mayen." In 1864 Captain Tobiensen sailed round North-East Land. In 1872 Captains Altmann and Nils Johnsen visited Wiche's Land, which was discovered by Captain Edge in 1617. In that year there were twenty-three sailing vessels from Tromsø, twenty-four from Hammerfest, and one from Vardø engaged in the Arctic sealing trade, averaging from 35 to 40 tons, and carrying a dozen men. Exploration went on slowly, in the course of the sealing and fishing voyages, the records of which are not very full. In 1869 Carlsen crossed the Kara Sea and reached the mouth of the Ob. In 1870 there were about sixty Norwegian vessels in the Barents Sea, and Captain Johannessen circumnavigated Novaya Zemlya. In 1874 Captain Tobiensen was unfortunately obliged to winter on the Novaya Zemlya coast, owing to the loss of his schooner, and both he and his young son died in the spring. Two years previously Captain Carlsen had succeeded in reaching the winter quarters of Barents, the first visitor since 1597, an interval of two hundred and seventy-four years. He landed on the 9th of September 1871, and found the house still standing and full of interesting relics, which are now in the naval museum at the Hague.

Between 1855 and 1872 the Swedes sent seven expeditions to Spitsbergen and two to Greenland, marking a new scientific era in Arctic exploration, of which Keilhau had been the pioneer. All returned with valuable scientific results. That of 1864 under A. E. Nordenskiöld and Duner made observations at 80 different places on the Spitsbergen shores, and fixed the heights of numerous mountains. In 1868, in an iron steamer, the "Sofia," the Swedes attained a latitude of 81° 42' N. on the meridian of 18° E., during the month of September. In 1872 an expedition, consisting of the "Holm" steamer and brig "Gladaen," commanded by Professor Nordenskiöld and Lieut. Palander, wintered in Moseel Bay on the northern shore of Spitsbergen. In the spring an important sledging journey of sixty days' duration was made over North-East Land. The expedition was in some distress as regards supplies owing to two vessels, which were to have returned, having been forced to stay. But in the summer of 1873 they were visited by Mr Leigh Smith, in his yacht "Diana," who supplied them with fresh provisions.

Dr. A. Petermann of Gotha urged his countrymen to take their share in the work of polar discovery, and at his own risk he fitted out a small vessel called the "Germania," which sailed from Bergen in May 1868, under the command of Captain Koldewey. His cruise extended to Hinnen Strait in Spitsbergen, but was merely tentative; and in 1870 Baron von Heuglin with Count Zeil explored the Spitz Fjord in a Norwegian schooner, and also examined Walter Land and Cape Espenberg, with the assistance of a regular expedition organized under the command of Captain Koldewey, provisioned for two years. It consisted of the "Germania," a screw steamer of 140 tons, and the brig "Hansa," commanded by Captain Hegemann. Lieut. Julius Payer, the future explorer of Franz Josef Land, gained his first Arctic experience on board the "Germania." The expedition sailed from Bremer on the 15th of June 1869, its destination being the east coast of Greenland. But in latitude 70° 46' N. the "Hansa" got separated from her consort and crushed in the ice. The crew built a house of patent fuel on the floe, and in this strange abode they passed their Christmas. In two months the current carried "Germania" 1,000 miles to the north, while "Hansa" continued 1,000 miles on their ice-raft, and finally, on the 14th of June 1870, they arrived safely at the Moravian mission station of Friedriksthal, to the west of Cape Farewell. Fairer fortune attended the "Germania." She sailed up the east coast of Greenland as far as 75° 30' N., and eventually wintered at the Pendulum Islands of Clavering in 74° 30' N. In March 1870 a travelling party set out under Koldewey and Payer, and reached a distance of 100 m. from the ship to the northward, when want of provisions compelled them to return. A grim cape, named after Prince Bismarck, marked the northern limit of their discoveries. As soon as the vessel was free, a deep branching fjord and promising island were explored, and the captain in 73° 15' N. stretching for a long distance into the interior of Greenland. The expedition returned to Bremen on the 11th of September 1870.

Lieut. Payer was resolved to continue in the path of polar discovery. He and the naval officer Weyprecht chartered a Norwegian schooner called the "Ishjorn," and examined the edge of the ice between Spitsbergen and Novaya Zemlya, in the summer of 1871. Their observations led them to select the route by the north end of Novaya Zemlya with a view to making the north-east passage. It was to be an Austro-Hungarian expedition, and the idea was seized with enthusiasm by the whole monarchy. Weyprecht was to command the ship, while Julius Payer conducted the sledge parties. The steamer "Tegethoff," of 300 tons, was fitted out in the Elbe, and left Tromsø on the 14th of July 1872. The season was severe, and the vessel was closely beset near Cape Nassau, at the northern end of Novaya Zemlya, in the end of August. The summer of 1873 found her still a close prisoner drifting, not with a current, but chiefly in the direction of the prevailing wind. At length, on the 31st of August, a mountainous country was sighted about 14 m. to the north. In October the vessel was drifted within 3 m. of an island lying off the main mass of land. Payer landed on it, and found the latitude to be 79° 54' N. It was named after Count Weyprecht, one of the warmest friends of the expedition. Here the second winter was passed. Bears were numerous and sixty-seven were killed, their meat proving to be an efficient preventive of scurvy. In March 1874 Payer made a preliminary sledge journey in intense cold (thermometer at −58° F.). On the 24th of March he started for a more prolonged journey of thirty days. Payer believed that the newly discovered country equalled Spitsbergen in extent, and described it as consisting of two or more large masses—Wilczek Land to the east, Zichy Land to the west, intersected by numerous fjords and skirted by a large number of islands. A wide channel, named Austria Sound, was supposed to separate the two main masses of land, and extend to 82° N. The whole country was named Franz Josef Land. Payer's large land-masses have by later discoveries been broken up into groups of islands and much of the land he thought he saw towards the east was found by Nansen not to exist. Payer returned to the "Tegethoff" on the 24th of April; and a third journey was undertaken to explore a large island named after M'Clinstock. It then became necessary to abandon the ship and attempt a return in boats. This perilous voyage was commenced on the 20th of May. Three boats stored with provisions were placed on sledges. It was not until the 14th of August that they reached.
the edge of the pack in 77° 40′ N., and launched the boats. Eventually they were picked up by a Russian schooner and arrived at Vardø on the 3rd of September 1874.

One of the most important expeditions connected with the physical geography of the polar regions is the actual condition of the vast elevated interior of Greenland, which is

**Nordenskiöld in Greenland.**

caused by the vast ice-cap being in constant motion, advancing slowly towards the sea. This movement gives rise to huge crevasses which bar the traveler's way. The chasms occur chiefly where the movement of the ice is most rapid, near the ice streams which reach the sea and discharge icebergs. Nordenskiöld therefore chose for a starting-point the northern arm of a deep inlet called Auletsivilkford, which is 60 m. south of the discharging glacier at Jakobshavn and 240 m. north of that at Godthaab. He commenced his inland journey on the 10th of July. The party consisted of himself, Dr Berggren, and two Greenlanders; and they advanced 30 m. over the glaciers to a height of 2200 ft. above the sea.

The gallant enterprises of other countries rekindled the zeal of Great Britain for Arctic discovery; and in 1874 the prime minister announced that an expedition would be despatched in the following year. Two powerful steamers, the “Alert” and “Discovery,” were selected for the service, and Captain George S. Nares was recalled from the “Challenger” expedition to act as leader. Commander Alfred H. Markham, who had made a cruise up Baffin Bay and Barrow Strait in a whaler during the previous year, Lieut. Pelham Aldrich, an accomplished surveyor, and Captain Henry Wemyss Feilden, R.A., as naturalist, were also in the “Alert.” The “Discovery” was commanded by Captain Henry F. Stephenson, with Lieut. Lewis A. Beaumont as first lieutenant. The expedition left Portsmouth on the 29th of May 1875, and entered Smith Sound in the last days of July. After much difficulty with drifting ice Lady Franklin Bay was reached in 81° 44′ N., where the “Discovery” was established in winter quarters. The “Alert” pressed onwards, and reached the edge of the heavy ice named by Nares the palaeocrustic sea, the ice-foes being from 80 to 100 ft. in thickness. Leaving Robeson Channel, the vessel made progress between the land and the grounded iced pieces, and passed the winter off the open coast and facing the great polar pack, in 89° 27′ N. Autumn travelling parties were despatched in September and October to lay out dépôts; and during the winter a complete scheme was matured for the examination of as much of the unknown area as possible, by the combined efforts of sledging parties from the two ships, in the ensuing spring. The parties started on the 3rd of April 1876. Captain Markham with Lieut. Farr advanced, in the face of great difficulties, over the polar pack to the latitude of 83° 20′ N. Lieut. Aldrich explored the coast-line to the westward, facing the frozen polar ocean; for a distance of 120 m. Lieut. Beaufort made discoveries of great interest along the northern coast of Greenland. The parties were attacked by scurvy, which increased the difficulty and hardships of the work a hundredfold. The expedition returned to England in October 1876. The “Alert” reached a higher latitude and wintered farther north than any ship had ever done before. The results of the expedition were the discovery of 300 m. of new coast line, the examination of part of the frozen polar ocean, a series of meteorological, magnetic and tidal observations at two points farther north than any such observations had ever been taken before, and large geological and natural history collections.

In the same year 1875 Sir Allen Young undertook a voyage in the steam yacht “Pandora” to attempt to force his way down Peel Sound to the magnetic pole, and if possible to make the north-west passage by rounding the eastern shore of King William Island. The “Pandora” entered Peel Sound on the 20th of August 1875, and proceeded down it much farther than any vessel had gone since it was passed by Franklin’s two ships in 1846. Sir Allen reached a latitude of 72° 14′ N., and sighted Cape Bird, at the northern side of the western entrance of Bellot Strait. But here ice barred his progress, and he was obliged to retrace his track, returning to England on the 16th of October 1875. In the following year Sir Allen Young made another voyage in the “Pandora” to the entrance of Smith Sound.

Lieut. Koolemans Beyen, a young Dutch officer, who had shared Young’s two polar voyages, on his return successfully endeavoured to interest his countrymen in polar discovery. It was wisely determined that the first expeditions of Holland should be summer reconnaissances on a small scale. A sailing schooner of 70 tons was built at Amsterdam, and named the “Willem Barents.” In her first cruise she was commanded by Lieut. A. de Bruyne, with Koolemans Beyen as second, and she sailed from Holland on the 6th of May 1876. Her instructions were to examine the ice in the Barents and Spitsbergen seas, take deep-sea soundings, and make natural history collections. Sir John Pelly was struck by the splendid memorials to early Dutch polar worthies at certain designated points. These instructions were ably and zealously carried out. Beyen died in the following year, but the work he initiated was carried on, the “Willem Barents” continuing to make annual polar cruises for many years.

In 1875 Sir Henry Gore-Booth and Captain A. H. Markham, R.N., in the Norwegian schooner “Ishjorn” sailed along the west coast of Novaya Zemlya to its most northern point, passed through the Matochkin Shar to the east coast, and examined the ice in the direction of Franz Josef Land as far as 75° 14′ N., bringing home collections in various branches of natural history, and making useful observations on the drift and nature of the ice in the Barents and Kara Seas.

In 1880 Mr B. Leigh Smith, who had previously made three voyages to Spitsbergen, reached Franz Josef Land in the polar steam yacht “Eira.” It was observed that, while the Greenland icebergs are generally angular and peaked, those of Franz Josef Land are flat on the top, like the Antarctic bergs. The “Eira” sailed along the south side of Franz Josef Land to the westward and discovered 110 m. of coast-line of a new island named Alexandra Land, until the coast trended north-west. A landing was effected at several points, and valuable collections were made in natural history. In the following year the same explorer left Peterhead on the 14th of July; Franz Josef Land was sighted on the 23rd of July, and the “Eira” reached a point farther west than had been possible in her previous voyage. But in August the ship was caught in the ice, was nipped, and sank. A hut was built on shore in which Mr Leigh Smith and his crew passed the winter of 1881–1882, their health being well maintained, thanks to the exertions of Dr W. H. Neale. On the 21st of June 1882 they started in four boats to reach some vessels on the Novaya Zemlya coast. It was a most laborious and perilous voyage. They were first seen and welcomed by the “Willem Barents” on the nth of August, and soon afterwards were taken on board the “Hope,” a whaler which had come out to search for them under the command of Sir Allen Young.

Professor A. E. Nordenskiöld, when he projected the achievement of the north-east passage, was a veteran explorer, for he had been in six previous expeditions to Greenland and Spitsbergen. In 1875 he turned his attention to the possibility of navigating the seas along the northern coast of Siberia. Captain Joseph Wiggins of Sunderland was a pioneer of this route,
and his voyages in 1874, 1875 and 1876 led the way for a trade
to the coasts of Europe and the mouth of the Yenisei River.

In June 1875 Captain Nordenskiöld sailed from
Tromsø in the Norwegian vessel, the "Proven," reached the Yenisei by way of the Kara Sea, and dis-
covered an excelent harbour on the eastern side of
its mouth, which was named Port Dickson, in honour of Baron
Oscar Dickson of Gothenburg, the munificent support of the
Swedish expeditions. It having been suggested that the success
of this voyage was due to the unusual state of the ice in 1875,
Nordenskiöld undertook a voyage in the following year in the
"Ymer," which was equally successful. By a minute study of
the history of former attempts, and a careful consideration of all the
circumstances, Nordenskiöld convinced himself that the
achievement of the north-east passage was feasible.
The king of Sweden, Baron Oscar Dickson, and M. Sibiriaoff, a
wealthy Siberian supplier, supplied the funds, and the steamer
"Vega" was purchased. Nordenskiöld was leader of the
expedition, Lieut. Palander was appointed commander of
the ship, and there was an efficient staff of officers and naturalists,
including Lieut. Hovgaard of the Danish and Lieut. Bove
of the Italian navy. A small steamer called the "Lena was
to keep company with the "Vega" as far as the mouth of
the Lena, and they sailed from Gothenburg on the 4th of July 1878.
On the morning of the 10th of August they left Port Dickson and
on the 10th they reached the most northern point of Siberia,
Cape Chelyuskin, in 77° 41' N. On leaving the extreme northern
point of Asia a south-easterly course was steered, the sea being
free from ice and very shallow. This absence of ice is to some
degree due to the mass of warm water discharged by the great
Siberian rivers during the summer. On the 27th of August the
course of the river Lena was passed, and the "Vega" parted
company with the little "Lena," continuing her course
eastward. Professor Nordenskiöld very nearly made the
north-east passage in one season; but towards the end of
September the "Vega" was frozen in off the shore of a low
plain in 65° 58' N. and 174° 29' W. near the settlements
of the Chukchis. During the voyage very large and impor-
tant natural history collections were made, and the interest-
ing aboriginal tribe among whom the winter was passed was
studied with great care. The interior was also explored for
some distance. On the 18th of July 1879, after having been
imprisoned by the ice for 294 days, the "Vega" again proceeded
on her voyage and passed Bering Strait on the 20th. Sir Hugh
Willoughby made his disastrous attempt in 1553. After a
lapse of 326 years of intermittent effort, the north-east passage had at length been accomplished without the loss of a single life and without damage to the vessel. The "Vega" arrived back in port on the 18th of August 1879.
In 1879 an enterprise was undertaken in the United States,
with the object of throwing further light on the sad history of
the retreat of the officers and men of Sir John Franklin's
expedition, by examining the west coast of King
William Island in the summer, when the snow is off the ground.
The party consisted of Lieut. Schwatka of the United States
army and three others. Wintering near the entrance of Chester-
field Inlet in Hudson Bay, they set out overland for the estuary
of the Great Fish river, assisted by Eskimos and dogs, on the
1st of April 1879. They took only one month's provisions,
their main reliance being upon the game afforded by the
region to be traversed. The party obtained, during the
journeys out and home, no less than 522 reindeer. After
collecting various stories from the Eskimos at Montreal Island and
at an inlet west of Cape Richardson, Schwatka crossed over to
Cape Herschel on King William Land in June. He examined
the western shore of the island with the greatest care for relics
of Sir John Franklin's parties, as far as Cape Felix, the northern
extremity. The return journey was commenced in November
by ascending the Great Fish river for some distance and then
marching over the intervening region to Hudson Bay. The cold
of the winter months in that country is intense, the thermometer
falling as low as -70° F., so that the return journey was most
remarkable, and reflects the highest credit on Lieut. Schwatka
and his companions. As regards the search little was left to be
done after McLennan, but some graves were found, as well as
a medal belonging to Lieut. Irving of H.M.S. "Terrier," and
some bones believed to be his, which were brought home and
interred at Edinburgh.

Mr Gordon Bennett, the proprietor of the New York Herald,
having resolved to despatch an expedition of discovery at his
own expense by way of Bering Strait, the "Pandora "
was purchased from Sir Allen Young, and rechristened
the " Jeannette." Lieut. de Long of the United States navy
was appointed to command, and it was made a national undertaking
by special act of Congress, the vessel being placed under martia
law. In July 1878, a six weeks' voyage was
undertaken from San Francisco on the 8th of July 1879, and the steamer
was throwing towards Wrangel Land on the 3rd of September. This land
had been seen by Captain Kellett, in H.M.S. "Herald" on the
17th of August 1879, but no one had landed on it, and it was
shown on the charts by a long dotted line. The "Jeannette"
was provisioned for three years, but as no tidings had been
received of her by 1881, two steamers were sent up Bering Strait in
search. One of these, the "Rodgers," under Lieut. Berry,
anchored in a good harbour on the south coast of Wrangel
Land, in 70° 57' N., on the 26th of August 1881. The land was
found to be an island about 70 m. long by 28, with a ridge of hills traversing it
east and west, the 71st parallel running along its southern
shore. Lieut. Berry then proceeded to examine the ice to the north-
ward, and attained a higher latitude by 21 m. than had ever
been reached before on the Bering Strait meridian—namely,
73° 44' N. No news was obtained of the "Jeannette," but soon
afterwards melancholy tidings arrived from Siberia. After
having been beset in heavy pack ice for twenty-two months, the
"Jeannette" was crushed and sunk on the 13th of June 1881, in
77° 15' N., lat., and 155° E. long. The officers and men dragged
their boats over the ice to an island which was named Bennett
Island, where they landed on the 29th of July. They reached
one of the New Siberia Islands on the 10th of September, and on
the 12th they set out for the mouth of the Lena. But in the
same evening the three boats were separated in a gale of wind.
A boat's crew with Mr Melville, the engineer, reached the Lena
delta and searching for the other parties found the ship's books
on the 14th of November, and resuming the search at the earliest
possible moment in spring, Melville discovered the dead bodies
of De Long and two of his crew on the 23rd of March 1882. They
had perished by exhaustion and want of food. Three survivors of
De Long's party had succeeded in making their way to a
law and officered from the navy. The "Nansen" was the
"Rogers" was the next to be seen; and one of the
officers, W. H. Gilder (1838-1900), made a hazardous journey
homewards through north-east Siberia.

The Norwegian geologist Professor Amund Hjelland made an
expedition to Greenland in 1875 and discovered the
marvellously rapid movements of the Greenland

Holland.

Danish in Greenland.

POLAR REGIONS
Cape Chelyuskin. He fitted out a small steamer called the "Dympna" and sailed from Copenhagen in July 1882, but was unfortunately beset and obliged to winter in the Kara Sea. In 1883 Baron A. E. Nordenskjöld undertook another journey over the inland ice of Greenland. Starting from Auletsivikfjord on the 4th of July, his party penetrated 84 m. eastward, and to an altitude of 5000 ft. The Laplanders who were of the party were sent farther on snow-shoes, travelling over a desert of snow to a height of 7000 ft. Useful results in physical geography and biology were obtained.

On the 18th of September 1875 Lieut. Weyprecht, one of the discoverers of Franz Josef Land, read a paper before a large meeting of German naturalists at Graz on the scientific results to be obtained from polar research and the best means of securing them. He urged the importance of establishing a number of stations within or near the Arctic Circle, and also a ring of stations as near as possible to the Antarctic Circle, in order to record complete series of synchronous meteorological and magnetic observations. Lieut. Weyprecht did not live to see his suggestions carried into execution, but they bore fruit in due time. The various nations of Europe were represented at an international polar conference held at Hamburg in 1879 under the presidency of Dr Georg Neumayer, and at another at Berne in 1880; and it was decided that each nation should establish one or more stations where synchronous observations should be taken for a year from August 1882. This fine project was matured and successfully carried into execution. The stations arranged for in the North Polar region were at the following stations:

The whole scheme was successfully accomplished with the exception of the part assigned to the Dutch at Port Dickson. They were prevented from doing "Varna," because they were obliged to winter there. The "Varna" was lost, and the crew took refuge on board Lieut. Hovgaard's vessel, which was also forced to winter in the pack during 1882-1883. The scientific observations were kept up on both vessels during the time they were drifting with the ice.

The American stations commenced work in 1882 and one of these furnished a rare example of heroic devotion to duty in face of difficulties due to the fault of those who should have brought relief at the appointed time. Lieut. A. W. Greely's party consisted of two other lieutenants, twenty sergeants and privates of the United States army, and Dr Pavy, an enthusiastic explorer who had been educated in France and had passed the previous winter among the Eskimo of Greenland. On the 11th of August 1881 the steamer "Proteus" conveyed Lieut. Greely and his party to Lady Franklin Bay during an exceptionally favourable season; a house was built at the "Discovery's" winter quarters, and they were left with two years' provisions. The regular series of observations was at once commenced, and two winters were passed without accident. Travelling parties were also sent out in the summer, dogs having been obtained at Disco. Lieut. Lockwood with twelve men and eleven sledges made a journey along the north coast of Greenland and reached Lockwood Island in 8° 3' 24" N. and 42° 45' W., the highest land they reached at that time. From this island at a height of 2600 ft. on a clear day an unbroken expanse of ice was seen stretching to the northward, the view extending far beyond the 84th parallel. A promontory of the north coast of Greenland seen to the north-east in 83° 35' N. was named Cape Washington. Vegetation was found at the extreme position and animal life was represented by foxes, hares, lemmings and ptarmigan. The party returned to Fort Conger on the 1st of June 1882 after an absence of 59 days. Greely made two journeys westward into the interior of Grinnell Land following up the northern branch of Chandler Fjord to a great sheet of frozen fresh water, Hazen Lake, with an area of about 500 square miles. Beyond this point, Lieut. Conger, he climbed Mt. Arthur, 4500 ft., the highest summit of Grinnell Land, and saw distant mountains beyond a fjord to the southwest. In the spring of 1883 Lockwood made still more extensive journeys, crossing Grinnell Land to Greely Fjord, which entered the western sea. The central depression of Grinnell Land abounded in musk oxen and was free from ice, though the higher land to north and south lay under permanent ice-caps. Important as these geographical discoveries were, the main object of the expedition was the series of scientific observations at the headquarters, and these were carried out during the whole period with the most scrupulous exactness. As neither the relief ship which was to have been dispatched in 1882, nor that in 1883, sent the expected relief to the station at Fort Conger, Lieut. Greely started from Lady Franklin Bay with his men in a steam launch and three boats on the 9th of August, expecting to find a vessel in Smith Sound.

The boats were beset and had to be abandoned, the party reaching the shore across the ice with great difficulty, carrying their supplies of food, now rapidly diminishing. On the 21st of October 1883 they were obliged to encamp at Cape Sabine, on the western shore of Smith Sound, and build a hut for wintering. A few dépôts were found, which had been left by Sir George Nares and Lieut. Beebe, but all supplies were exhausted before the spring. They came a time of indescribable misery and acute suffering. The party prided insubordinate and the sternest measures were required to maintain military discipline. When the sun returned in 1884 the poor fellows began to die of actual starvation; but it was not until the 22nd of June 1884 that the relieving steamers "Thetis" and "Bear" reached Cape Sabine. Lieut. Greely and six suffering companions were found just alive, but with all their scientific records, their instruments in order and the great collections of specimens intact. The failure of the relief expeditions to overcome difficulties which were child's play to what Greely and his companions had come through only enhances the splendid courage and determination of the heroic survivors.

In the following year, Danish Lieut. G. Holm explored the east coast of Greenland from Cape Farewell northwards in Eskimo boats between 1883 and 1885, and at Angmagssalik they encountered a tribe of Eskimo who had never seen white men before. Lieut. Ryder and Lieut. T. V. Garde continued the exploration of East Greenland, and Ryder explored the great Scoresby Fjord. Captain Holm established a missionary and meteorological station at Angmagssalik Fjord in 1894, from which the Danish government take charge of the Eskimo of that region. In 1892-1893 an expedition sent out by the Berlin Geographical Society under Dr Erich von Drygalski studied the ice formations on the west of Greenland.
traversed 260 m. of glacier. Nansen discovered that in that latitude the inland ice of Greenland has the form of a huge shield rising rather rapidly but regularly from the east coast to nearly 3000 ft., flat and even in the middle, but falling again regularly toward the western side, completely enveloping the land. An important principle acted on for the first time in Arctic travel on this journey was that of starting from the less accessible side and pushing straight through with no possibility of turning back, and thus with no necessity for forming a base or traversing the same route twice.

Peary spent the winter of 1891–1892 at Inglefield Gulf on the north-west coast of Greenland, Mrs Peary, Dr F. A. Cook, Evlinda Austrup and a coloured servant Matthew Henson being in his party, and a large number of the Etah Eskimo in the vicinity. In April 1892 he set out for a journey across the inland ice to the north-eastward in the hope of reaching the coast and also the northern extremity of the land. After getting well up on the ice-covered plateau a supporting party returned to winter quarters, while Peary and Austrup, with two companions and sixteen dogs, entered on the serious part of their work. The highest part of the inland ice was found to be about 3500 ft., and as usual after the first part of the descent, towards the north-east in this case, the surface was broken by numerous dangerous crevasses, progress amongst which was very slow. Great hardships were experienced from cold, insufficiency of food and the wearing out of sledges and clothes, but on the 4th of July, having left the ice and got on bare land in 81° 37' N., where musk-oxen and other game were found and flowers growing, Peary was rewarded by a glimpse of the sea to the north-eastward, and named it from the date Independence Bay. He also traced a channel to the north beyond which lay a new land largely free from snow, no doubt the southern part of the island along the north of which Markham and Lockwood had travelled to their farthest north. The return journey to Inglefield Gulf was a wonderful feat of endurance, which was completed on the 4th of August; the total distance marched on the whole journey out and home was 1300 m. Peary returned to northern Greenland in 1893, having spent the whole time between the two expeditions in writing and lecturing in order to raise funds, for he travelled at his own charges. He landed on the shore of Inglefield Gulf on the 3rd of August and wintered there with a party of thirteen, including Mrs Peary, and there their daughter was born. Austrup was taken ill after starting on the great journey in March 1894, which was to have extended the explorations of the previous year, and had to return; others were severely frost-bitten, disease broke out amongst the dogs, and a month after the start Peary was only 130 m. from his base and had to return. Peary with two of his party, Hugh J. Lee and Matthew Henson, remained at Inglefield Gulf for another winter, and on the 1st of April 1895, with deer and walrus meat in place of pemmican, the supply of which had been lost, set out for Independence Bay. They reached the ice-free land when their food was exhausted and fortunately fell in with a herd of musk oxen, the meat from which made it possible to get back to Inglefield Gulf, though without adding anything material to the results of 1892. The experience of ice-travel and of Eskimo nature gained in the four years' almost continuous residence in northern Greenland were however destined to bear rich fruit.

Dr Nansen, after making an exhaustive study of the winds and currents of the Arctic Sea, and influenced largely by the occurrence of driftwood on the shores past which the ice-laden waters flowed southward between Greenland and Spitsbergen, satisfied himself that there was a general drift across the polar basin and perhaps across the Pole. He decided to attempt to take advantage of this drift on the principle which guided his crossing of Greenland, that of entering at the least accessible point and not turning back, thus having no line of retreat and making a relief expedition impossible. He planned a ship, the “Fram,” which was immensely strong, to resist crushing, and of such a section that if nipped in the ice the opposing ice-masses would pass under her and lift her on to the surface. The plan of the expedition was based on scientific reasoning, but the methods were totally at variance with those of previous explorers. Otto Sverdrup, who had been one of Nansen's party in crossing Greenland, was captain of the expedition, and he had secured the services of a company of thirteen living together on terms of social equality. Nansen paid the greatest possible attention to the provisions, and all the arrangements for the health and happiness of those on board were carefully thought out. The clothing of the expedition was as original in design as the ship; instead of having furs, thick woolen underclothing was adopted, with a light wind-proof material for the outer dress. The “Fram” left Christiania in the summer of 1893 and made her way through the Kara Sea and along the north coast of Asia until on the 20th of September she was run into the ice in 77° 30' N., off the New Siberia Islands, and the great drift commenced. As anticipated, she rose to the pressure of the ice and was borne on an even keel high above the water for the whole duration of the drift. The movement of the ice was irregular, and on the 7th of November the “Fram” was back at her starting-point, but on the whole the movement was north-westward until the 15th of November 1895, when the highest latitude of the ship was attained, 83° 55' N. in 66° 31' E., the meridian of the east of Novaya Zemlya; then it was westward and finally southward until the ice was broken by blasting round the ship in June in 83° N. lat.; and after being aloof, though unable to make much progress until the middle of July, the “Fram” broke out of the ice off the north coast of Spitsbergen on the 13th of August 1896. No ship before or since has reached so high a latitude. In all her drift the “Fram” came in sight of no new land, but the soundings made through the ice proved that the Arctic Sea was of great depth, increasing towards the Pole, the greatest depth exceeding 2000 fathoms. The great mass of water filling the polar basin was comparatively warm, indicating free circulation with the Atlantic. It was established that the ice formed off the coast of Asia drifted across the polar basin in a period of from three to five years, and the hypothesis on the truth of which Nansen risked his success was abundantly verified by facts. The ship's company all returned in perfect health. After the second winter on the “Fram” at a time when the northward movement of the drift seemed to be checked, Nansen, accompanied by Lieut. Hjalmar Johansen, left the ship in order to explore the regions towards the Pole by travelling on ski with dog sledges carrying kayaks. It was obviously hopeless to attempt to find the drifting ship on their return, and Nansen intended to make for Spitsbergen in the hope of meeting one of the tourist steamers there. A more daring plan was never formed, and it was justified by success. Leaving the ship on the 14th of March 1895 in 84° N. 102° E., they made a fairly rapid march northward, reaching a latitude of 86° 5' N. on the 8th of April, the nearest approach to the Pole so far achieved. Turning south-westwards they travelled with much difficulty, sometimes on the ice, sometimes in kayaks in the open lanes of water, incurring great danger from the attacks of bears and walrus, but at length reaching a group of new islands east of Franz Josef Land. They travelled westward through this archipelago until the 28th of August, when they built a small stone hut roofed with their light silk tent, in which they passed the winter on a land since called Frederick Jackson Island. There they lived like Eskimo on bear and walrus meat cooked over a blubber lamp. The journey southward was resumed in the spring of 1896, and on the 15th of June they met Mr F. G. Jackson, in whose relief ship, the “Windward,” they returned to Norway. Nansen and Johansen reached Tromsö on the 13th of August 1896. Mr Frederick George Jackson planned an exploring expedition

**Drift of the “Fram”**
to attain a high latitude by the Franz Josef Land route and was supported financially by Mr A. C. Harmsworth (Lord Northcliffe). He was accompanied by Lieut. Albert Harmsworth Armitage, R.N.R., as second in command and six scientific men, including Dr Reginald Koetttitz; Dr W. S. Bruce was also one of the number in the second year. The Jackson-Harmsworth expedition sailed from Spitzbergen in June, 1904, and was landed at Cape Flora, where log houses were built. In the spring of 1893 Jackson made a journey northward to 81° 19' N., the highest latitude reached, and added considerably to our knowledge of the archipelago by discovering a channel between groups of islands west of the Austria Sound of Payer. He made numerous other journeys by land and in boats, and surveyed a considerable portion of the islands on which he landed, the most interesting being that of 1897, to the western portion of the group. The geological collections were of some value and the specimens secured indicated that Franz Josef Land and Spitsbergen were parts of an extensive land existing in Tertiary times. The expedition returned in 1897.

In 1897 and subsequent years a party led by Sir Martin Conway explored the interior of Spitsbergen. Dr A. C. Nathorst, the Swedish geologist, explored the eastern coast and off-lying islands, and made important observations on North-East Land, circumnavigating the Spitsbergen archipelago in 1898. In 1899 Nathorst visited the north-east coast of Greenland in search of André's balloon expedition, and here he mapped Franz Josef Fjord and discovered the great King Oscar Fjord in waters that had never been navigated before.

In subsequent years valuable surveys and scientific observations were made by the Prince of Monaco in his yacht 'Princesse Alice,' by Dr W. S. Bruce, notably on Prince Charles Foreland, and by others. Franz Josef Land was visited by the American explorer W. Wellman in 1898 and 1900, and his companion E. Baldwin in the former year made the discovery of several islands in the east of the archipelago. A wealthy American, W. Zeigler, also sent out expeditions to Franz Josef Land in 1901 and between 1903 and 1905, in the course of which A. Fiala reached the high latitude of 82° 4' N. in the 'America,' but the ship was afterwards lost in Tepiltz Bay. These expeditions added little to our knowledge of polar geography, but some useful meteorological, magnetic and tidal observations were made.

The Italian expedition under the command of H.R.H. Prince Luigi, duke of Abruzzi, was the most successful and all the parties which have attempted to reach high latitudes by way of Franz Josef Land. Embarking in the summer of 1899 on the "Stella Polare" (formerly the Norwegian whaler "Jason") which had landed Nansen on the east coast of Greenland in 1888, the expedition put into Tepiltz Bay in Rudolf Land, where they wintered and there the ship was seriously damaged by the ice. In the spring of 1900 a determined effort was made to reach the North Pole by sledging over the sea-ice. The duke of Abruzzi having been disabled by frost-bite, the leadership of the northern party devolved upon Captain Umberto Cagni of the Italian navy, who started on the 19th of March 1900 with ten men (Alpine guides and Italian sailors) and nearly a hundred dogs. His plan was to sled northward over the sea-ice, sending back two parties as the diminishing stores allowed the advance party to take on the whole of the supplies destined to support them on their way to the Pole and back. Before losing sight of Rudolf Island three men forming the first party started to return, but they never reached winter quarters and all must have perished. The second party went back from latitude 83° 10' N., and reached their base in safety. Cagni pushed on with three companions, determined if he could not reach the Pole at least to outdistance his predecessor Nansen, and on the 25th of April 1900 he succeeded in reaching 86° 14' N., and the expedition made it necessary to turn at this point, and although he had reached it in 45 days it took Cagni 60 days to return. The advance of summer loosened the ice-floes, and the westward component of the drift of the pack became a more and more serious danger, threatening to carry the party past Franz Josef Land without sighting it. Fortunately Cape Mill, a headland of characteristic outline, was sighted just in time, and with this as a guide the party succeeded in reaching Tepiltz Bay, having eaten the last of their dogs and been reduced to great extremities. At the farthest north no land was visible, the rough sea-ice extending to the horizon on every side.

As early as 1895 a scheme for an exploring expedition in a balloon was put forward seriously, and in 1897 the Swedish aeronaut S. A. André carried it out. He had brought a balloon to Danes Island, in the north of Spitsbergen, the previous year, but the weather was unpropitious and the ascent had to be postponed. On the 11th of July 1897 he started in a new and larger balloon with about five tons of supplies and two companions. It was hoped that the balloon could be steered to some extent by the use of heavy guide ropes dragging over the ice, and André had already made successful flights in this way. Rising at 2.30 p.m. the balloon was out of sight of Danes Island in an hour. At 10 p.m. André threw out a buoy containing a message which was recovered, and this stated that the balloon was in 82° N. 25° E., moving towards the north-east at an altitude of 800 ft. above a rugged ice-field. This was the last news received, and although scarcely a year has passed without some rumour of the balloon having been found in Siberia or North America, nothing further has ever been ascertained.

In 1899 Admiral Makaroff of the Russian navy arrived for the trial trip of the great ice-breaker "Yermak," which he designed, to take the form of an expedition into the sea-ice off Spitsbergen. Though no high latitude was attained on this occasion he formed the opinion that a vessel of sufficient size and power could force a passage even to the Pole. The Russian-Japanese War put an end to the polar projects of this gifted man of science.

Captain Otto Sverdrup, who had been Nansen's companion on his two polar expeditions, planned an Arctic voyage for the circumnavigation of Greenland, and the "Fram" was altered and refitted to suit her for the work. Starting in 1899, he was obliged to abandon the attempt to get northward through Smith Sound, and making his way westward into Jones Sound he spent three years in exploring and mapping the portion of the Arctic archipelago which lay to the north of the field of labour of the Franklin search expeditions. Ellesmere and Grinnell islands were shown to be part of one large land mass called King Oscar Land, which is separated by a narrow channel, Eureka Sound, from an extensive island named Axel Heiberg Land. Two of his party (Isachsen and Hassel) discovered and explored two islands west of Heiberg Land, and Dr Scheie made most valuable observations on the geology of the whole of the district examined. Sverdrup's journeys cleared up a great deal of uncertainty regarding the geography of the least known portion of the Arctic archipelago, and leave little more to be done in that quarter. He brought the "Fram" safely back to Norway in 1903.

Many American whalers working in the sea reached through Bering Strait believe that land of considerable extent lies farther west than the Arctic archipelago, north of the mouth of the Mackenzie River, but neither the English traveller A. H. Harrison in 1905, nor the Dane Einar Mikkelsen in 1907, was able to find any trace of it, though the latter sailed over the sea ice as far as 72° N., where in 150° W. he got a sounding of 330 fathoms with no bottom. This depth makes it somewhat improbable that land exists in that quarter.

Russian surveyors and explorers continued to map portions of the Siberian coast, and in 1886 Dr Bunge and Baron Toll visited the New Siberia Islands and made known the remarkable remains of mammoths which exist there in great numbers. In 1893 Baron Toll made an important geological expedition to the islands, discovering many well-preserved remains of mammoths and other extinct mammals and finding evidence that in the mammoth period trees grew at least as far as 74° N. Indefatigable in the pursuit of his studies, Toll set out once more in 1901 on board the
"Zarya," hoping to reach Sannikof Island, the most northerly and still unvisited portion of the New Siberia group. In August 1902 he reached Benett Island with the astronomer Sargent. After spending the winter there, he found the island to be a plateau about 1900 ft. in elevation, and remained there until November exploring the geological features. Nothing more was heard of the expedition, and a relief expedition in 1904, under Lieuts. Brusnelf and Kolchak, failed to find any trace of the explorers beyond a record left on Benett Island, which gave a summary of their movements up to the time of leaving the island.

In 1901 Captain Rould Amundsen, a Norwegian, who had been mate on the "Belgica" in her Antarctic voyage, planned an expedition to the area of the north magnetic pole visited by Sir James Ross in 1831, in order to re-locate it, and as a secondary object he had in view the accomplishment of the North-West Passage by water for the first time, McClure not having carried his ship through from sea to sea. A small Norwegian sealing sloop, the "Gjøa," the cabin of which measured only 9 ft. by 6, was fitted with a petroleum motor engine of 30 h.p. for use in calm weather and strengthened to withstand ice-pressure. She left Christiania on the 17th of June 1903 with a total company of six men, second in command being Lieut. Godfred Hansen of the Danish navy. She passed through Lancaster Sound and worked her way down the west side of Boothia Felix, in August, and took up winter quarters in Gjøa Harbour at the head of Petersen Bay, in King William Land. Here the little vessel remained for five years, when a few more observations were carried out, and sledging excursions were made to the magnetic pole and along the coasts of Victoria Land, which was charted up to 72° N. In August 1905 the "Gjøa" proceeded westward along the American coast but was frozen in off King Point for a third winter. On the 11th of July 1906 she got free, and after much difficulty with the ice reached Bering Strait on the 30th of August and entered the Pacific, the first ship to pass from ocean to ocean north of Patagonia.

Danish explorers have continued to concentrate their attention on the problems of Greenland, and especially the geography of the east coast. Lieut. H. D. Amdrup, in a series of expeditions between 1898 and 1900, charted the coast-line as far north as 79° 15' N., and made important scientific observations and collections. From time to time whalers reached the east Greenland coast at points in high latitudes. The duke of Orleans in the "Belgica," under the command of Captain Gerlache, made an important voyage in 1905, in the course of which he cruised along the coast of Germany Land between 76° and 78° N., and fixed the general outline of the land up to that latitude. This expedition did a large amount of scientific work, especially in oceanography. The stream of ice-which presses outwards from the polar basin every summer bears close against the east coast of Greenland, and exploration by sea has always proved exceedingly difficult and precarious, success depending very much on the occurrence of chance leads amongst the ice.

Taking advantage of all previous experience, the most important of the Danish expeditions was planned by L. Mylius-Erichsen in 1905, the expenses being partly raised by private subscriptions and partly provided by the Danish government. He sailed in the "Danmark" in June 1906 and found winter quarters in Danmarkhaven, 75° 43' N., where the ship remained for two years, while systematic magnetic and meteorological observations were kept up at the base and the main work of exploring to the northward was carried on by sledge. From existing maps it was believed that about 620 m. of coast separated the winter quarters from the northern point of Greenland, but when the sledging expedition went out in 1907 the coast was found to curve much farther to the eastward than had been anticipated, and the outward journey extended to 800 m. Having left the winter quarters on the 28th of March 1907, Mylius-Erichsen, with Captain Koch, Hagen, an educated Eskimo, Brølund and two others, reached North-East Foreland, the eastern extremity of Greenland (84° 20' N., 11° 15' W.). Here they divided; Koch with Bertheisen and the Eskimo Tobias went north-westward to explore the east coast of Peary Land, and succeeded in reaching the northwestern extremity of the land beyond Cape Bridgman in 85° 30' N. From this great journey he returned in safety to winter quarters, arriving on the 24th of June. Meanwhile Mylius-Erichsen, with Hagen and the Eskimo Brølund, followed the coast westward into what was believed to be the Independence Bay seen from a distance by Peary; this turned out to be a deep inlet now named Danmark Fjord. Keeping to the coast, they entered the great channel separating the mainland of Greenland from Peary Land, and surveyed Hagen Fjord on the southern shore and Brølund Fjord on the northern shore of the strait. They had pushed on to Cape Glacier in 83° 10' N. and 35° W. by the 14th of June 1907, within sight of Navy Cliff, which had been Peary's farthest coming from the west side, and here the softness of the snow kept them all summer. When they finally decided to go ashore they found a large ice-rafted on a floe in the effort to cross Danmark Fjord. Here the sun left them, while they were without food, almost worn out and more than 500 m. from the ship. It was impossible to attempt the long journey round the coast, and the only chance of safety, and that a very slender one, was to make a way southward over the inland ice and so cut off the eastern horn of Greenland which the expedition had discovered. Under the most terrible difficulties, with only four starved dogs, and their equipment going to pieces, they accomplished the feat of marching 160 m. in 26 days, and reached the east coast again in 79° N.

On the way, Mylius-Erichsen himself struggled on until he nearly reached the provisions left on Lambert Island on the northern journey; but he too perished, and only Brølund reached the supplies. He was frost-bitten and unable to proceed further, and after recording the tragedy of the return journey in his diary, he died also alone in the Arctic night. His body and the records of the great journey were discovered in the following year by Koch, who started on a relief expedition as soon as travelling became possible. The results of this expedition are a splendid monument to the courage and devotion of the leader and his followers. The channel between Spitsbergen and Greenland was shown by their efforts to be far narrower than had previously been supposed, and the outline of Greenland itself was fixed for the first time, and that by an extremely accurate survey.

There only remains one further episode to bring the history of polar exploration up to 1910, but that is the crowning event of four hundred years of unceasing effort, the attainment of the Pole itself; and it was accomplished by the undaunted perseverance of one man who would never accept defeat. After the return of the Jackson-Harmsworth expedition, Lord Northcliffe presented the "Windward" to Lieut. Peary, who resumed in 1898 his systematic explorations of the Smith Sound region in the hope of finding the Pole. He was not restrained by the precedents of earlier travellers and made some long sledge journeys in the winter of 1889-1890, having his feet badly frost-bitten and losing eight toes. Even this crippling did not stop his work. He wintered amongst the Etah Eskimo in 1890-1900 and next spring made a successful journey to the most northerly land north of Greenland in 83° 35' where the land had an abundant flora and fauna, and he pushed north over the sea-ice for twenty miles farther, reaching 83° 54' N. Peary wintered again at Fort Conger in 1900-1901, and for the fourth year in succession he went through the Arctic winter, 1901-1902, at Payer Harbour. In the spring of 1902 he made a great journey to Cape Hecla in the north of Grant Land and thence northward over the frozen sea to 84° 15' N. in 70° W. Frequent open leads of water and the moving of the ice-floes made further advance impossible, and after an unparalleled sojourn in the farthest north, Peary returned to the United States. The Peary Arctic Club of New York, formed to support this indomitable explorer, provided funds for a new expedition and a ship differing in some respects from those hitherto employed and named the "Roosevelt." In her he proceeded in the summer of 1905 through Smith Sound and the northern channels to Cape Sheridan on the north coast of Grant Land,
The return journey was quick and easy. The tracks kept open by the passage of the various return parties were distinct enough to follow, the snow-houses stood ready for sheltering at the end of each march, and a northerly gale kept the ice pressed well together and the leads closed. On the 23rd of April a column was abandoned to the sea after the party was safe on board the "Roosevelt." Success was due to the accumulated experience of twenty-three years' constant Arctic work, and to the thorough acquaintance with the Eskimo and their dogs, which enabled the best work to be got out of them.

Dr. F. A. Cook spent two years in the Arctic regions, 1907–1909, and claimed to have reached the Pole by sledging alone with two Eskimos a year before Peary. He submitted the evidence for this achievement to the university of Copenhagen, which failed to find it satisfactory, and Dr. Cook did not appear to challenge this decision.

**Physiography of the Arctic Region**

**Geology.**—Although much remains to be done in the exploration of the North Polar area, the main features of the physical geography of the region have been determined beyond any reasonable doubt. Within the Arctic Circle the northern portions of Europe, Asia, America and Greenland surround a central area of deep sea, the southern margin of which forms a broad continental shelf bearing many islands. The ring of land and shallow sea is broken only by the broad channel between Greenland and Europe through which Atlantic water gains an entrance to the Arctic Sea. The physical conditions of this sea, which covers the greater part of the Arctic regions, are dealt with later in detail; but there is less to be said regarding the land.

In a climate which taxes human powers to the utmost to carry on the simplest route-surveys in the course of an exploring expedition, and in the presence of a snow covering which is permanent on all high ground and only disappears for a short time in summer, even on the shores and islands, it is obvious that any knowledge of the geology must be difficult to obtain. On the earlier Arctic expeditions enthusiastic collectors brought together quantities of specimens, many of which it was found impossible to bring home, and they have been found abandoned by later travellers. As Arctic exploration was usually carried out on the sea or over the sea-ice even those expeditions in which experienced geologists took part furnished few opportunities for making investigations. The result is that the geology of the Arctic lands has to be inferred from observations made at isolated points where the fortune of the ice stopped the ship, or where on land journeys a favourable exposure was found. Almost every geological formation is known to be represented, from the Archaean to the Quaternary, and there is a general resemblance in the known geological features of most of the great Arctic islands. The fundamental rock in all appears to be Archaean gneiss. In the extreme north-east Carboniferous strata have recently been discovered similar to the Carboniferous rocks of Spitsbergen. The Jurassic rocks farther south are in places capped by Cretaceous beds, and closely resemble the Jurassic rocks of Spitsbergen, Franz Josef Land and the northern parts of Norway and Russia. Cretaceous and Tertiary rocks are found on the west coast of Greenland covered over by great flows of basalt, probably of Tertiary age, at Disco Island, Nugsuak Peninsula and various points farther north. The only mineral of economic value found in Greenland is cryolite, which is mined at Iqivit in the south-west. Native iron occurs in considerable masses in several places, some of it undoubtedly of telluric origin, though some is probably of the old mass.

The second "Fram" expedition confirmed and extended the geological observations of the Franklin search expeditions on the American Arctic archipelago, and showed the presence above the Archaean rocks of Cambrian, Silurian and Devonian strata, the Silurian being represented by a widespread brown limestone abounding in fossils. Carboniferous limestones also occur and less extensive beds of quartz sandstones, schists and limestones containing ammonites and other Mesozoic fossils. Tertiary

From the North Pole Expedition, 1893-1896, Scientific Results, edited by Fridtjof Nansen, by permission of the Fridtjof Nansen Fund for the Advancement of Science.
rocks including beds of lignite and plant fossils of Miocene age also occur, and they are interstratified and overlapped with basalt and other eruptive rocks as in Greenland. In Grant Land Tertiary coal occurs in Lady Franklin Bay (8° 45' N.), the most northerly deposit of fossil fuel known. Arctic Canada consists of Archaean and Palaeozoic rocks worn down into plateaux or plains and bearing marks of glacial action, the absence of which is the most remarkable feature of the tundra region of Siberia. The Siberian coast is superficially formed to a large extent of frozen soil and gravel sometimes interbedded with clear ice, and in this soil the frozen bodies of mammoths and other Quaternary animals have been found preserved in a fresh condition by the low temperature. The absence of a glacial period in northern Siberia is probably indirectly due to the very low temperature which prevailed there, preventing the access of water vapour from without and so stopping the supply required to produce sufficient precipitation to form glaciers or ice-caps. On the New Siberia Islands Silurian and Tertiary rocks have been recognized, the latter with abundant deposits of fossil wood.

The geological evidence is complete as to the existence of a genial climate in Tertiary times as far north as the present land extends, and of a climate less severe than that of to-day in the Quaternary period. The existence of raised sea margins in many Arctic lands and especially in the American Arctic archipelago bears evidence to a recent elevation of the land, or a withdrawal of the sea, which has been influential in forming some of the most prominent features of the present configuration.

It is noteworthy that no great mountain range runs into the Arctic region. The Rocky Mountains on the west and the Ural range on the east die down to insignificant elevations before reaching the Arctic Circle. The plateau of Greenland forms the loftiest mass of Arctic land, but the thickness of the ice cap is unknown. The one active volcano within the Arctic Circle is on the little island of Jan Mayen.

The Arctic Climate.—As the water of the Arctic Sea is free from ice around the margin only for a few months in summer, and is covered at all times over its great expanse with thick ice in slow uneasy motion, there is less contrast in climate between land and sea, especially in winter, than in other parts of the world. The climate of the polar area may be described as the most characteristic of all the natural features, and observations of temperature and pressure are more numerous and systematic than any other scientific observations. The Russian meteorological system includes Siberia, and long series of observations exist from stations up to and within the Arctic Circle. The Canadian Meteorological Service has secured like observations for the extreme north of North America, though the records are more fragmentary and of shorter duration. Norway and Iceland also yield many records on the margin of the Arctic Circle. The international cirum-polar stations maintained during 1882 connected the Siberian, Norwegian and Canadian land stations with the more fragmentary work of the various polar expeditions which have wintered from time to time in high latitudes. The most valuable records and practically the only data available for the climate north of 84° are those of the first expedition of the "Fram" in her three years' drift across the polar basin. Later expeditions beyond the 84th parallel were merely dashes of a few weeks' duration, the records from which, however accurate, are of an altogether different order of importance. The data collected by the "Fram" were discussed in great detail by Professor H. Mohn in 1904, and that eminent authority combined them with all that had been known previously, and all that was ascertained by later explorers up to the return of Captain Sverdrup from the second "Fram" expedition, so as to give the complete account ever attempted of the climate of the North Polar regions, and on this we rely mainly for the following summary.

Temperature.—From Professor Mohn's maps of the isotherms north of 60° N. it is evident that the temperature reduced to sea-level is lowest in the winter months within an area stretching across the pole from the interior of Greenland to the middle of Siberia, the long axis of this very cold area being in the meridian of 40° W. and 140° E. For every month from October to April the mean temperature of this cold area is below 8° F., and in the two coldest months there are three very cold areas or poles of cold with temperatures below -40° arranged along the axis. These are the interior of Greenland, an area around the North Pole and the centre of Northern Siberia. Professor Mohn is satisfied that these three poles of cold are separated by somewhat warmer belts, as observations on the north coast of Greenland show a temperature higher both than the temperature of the interior reduced to sea-level and the temperature on the frozen sea farther north. As summer advances the temperature rises to the freezing point most rapidly in North America, the mean temperature for July, August and September on the American coast and the Arctic archipelago being above the freezing point. In July and August the Arctic shores in America, Asia and Europe have a mean air-temperature of about 40° F., but the interior of Greenland and the area around the North Pole remain below 32°, those two poles of cold persisting throughout the year while the winter cold pole in Asia disappears in summer.

There is no reason to doubt that in winter the Asiatic area is the coldest part of the Arctic region, and as it is permanently inhabited it is plain that low temperature alone is no bar to the wintering of expeditions in any part of the North Polar region.

The lowest temperature experienced during the drift of the "Fram" was -62° F., on the 12th of March 1884 in lat. 70° 41' long. 134° 17' E. The minimum temperatures recorded on Sir George Nares' expedition were -73°-8° F. on the "Alert" in 82° 29' N. and -70°-8° on the "Discovery" in 81° 44' N., both in March 1876, and the minimum on Sverdrup's expedition in Jones Sound in 76° 50' N. was -60° F. in January 1901. In February 1882 Greely recorded -66°-2° at Fort Conger, 81° 44' N., and at Fort Constance in Canada (66° 40' N. 110° W.) a temperature of -72° F. was noted in January 1851. The lowest temperature ever recorded on the earth's surface was probably that experienced at Verkhoyansk in Siberia (67° 34' N.) where the absolute minimum in the month of February was -93°-6', and minima of -70° or more have been recorded in every winter month from November to March inclusive, and as the absolute maximum in July was +02°-9° the total range experienced is no less than 186°-5°, far exceeding that known in any other part of the world.

The normal monthly mean temperatures for various parallels of latitude are given as follows by Professor Mohn, the last column showing the calculated conditions at the North Pole itself expressed to the nearest degree.

The interior of Greenland is believed to be below the normal temperature for the latitude in all months and so is the region between Bering Strait and the Pole; the Norwegian-Sea, and the region north of it as far as the Pole, has a temperature above the normal for the latitude in all months; while the temperature

1It must be remembered that for cartographical purposes temperature is reduced to its value at sea-level, allowing for a change of 1° F. in about 100 ft. This is certainly correct for the snowcap of Greenland at the height of 9000 ft. is 30° F. lower at all seasons than is shown on an isothermal map, and that of Verkhoyansk (500 ft.) is only 1°-5° F. lower than charted.
POLAR REGIONS

In the northern continents is below the normal in winter and above the normal in summer. The "Fram" observations showed that while the ordinary diurnal range of temperature prevailed for the months when the sun was above the horizon during some part of the day, there was also a diurnal range in the winter months when the sun did not appear, the minimum then occurring about 2 p.m. and the maximum about 1 a.m., the "day" being colder than the "night." Except in July and August the temperature was always found to be lower with the weaker winds and higher with the stronger winds irrespective of direction. Extraordinarily rapid variations of temperature have been observed in the winter months, on one occasion in February 1896 (north of 84°N.) the thermometer rising within 24 hours from −45°4′ to +22°3′F., a rise of 67°7′.

Cloud and Precipitation.—The amount of cloud in the far north is greater in the daytime than at night, the summer months being cloudy, the winter very clear, and the amount is greater with the stronger winds and less with the weaker winds. Precipitation is most frequent in the summer months, the "Fram" results showing an average of 20 days per month from May to September; while from October to April the average was only 11 days per month. Rain was only observed in the months from May to September; but snow occurs in every month and is most frequent in May and June, least frequent in November and December, which are the months of minimum precipitation. It has never been possible to make satisfactory measurements of the amount of precipitation in the Arctic regions on account of the drifting of snow with high wind. Fogs occur most frequently in July and August (20 or 16 days per month); they are practically unknown between November and April.

Pressure.—The "Fram" observations enabled Professor Mohn to revise and extend the isobaric maps of Dr Buchan, the correctness of which was strikingly confirmed. The Atlantic and Pacific low pressure areas are found at all seasons on the margin of the Arctic area, the position shifting a little in longitude from month to month. The two low pressures are separated in the winter months by a ridge of high pressure (exceeding 30-00 in.) stretching from the Canadian to the Siberian side between the North Pole and Bering Strait; this ridge has been termed by Professor Suan "the Arctic wind divide." In April the high pressure over Asia gives way and an intense low pressure area takes its place during the summer, uniting in August with the less intense low-pressure area which develops later over Canada, and reducing the Arctic high pressure area to an irregular belt extending from North Greenland to Franz Josef Land on the Atlantic side of the Pole. The general pressure over the polar area is much higher in winter than in summer and the gradients are steeper also in the cold weather, giving rise to stronger winds. The isobaric conditions indicate light variable winds in summer along the route of the "Fram" from the New Siberia Islands to the north of Spitsbergen, and in winter south-easterly or easterly winds of greater force; this is in accord with the observations made during the drift. Professor Mohn believes that the maximum pressure at the North Pole takes place in April, when it is about 30-08 in.; and the minimum pressure from June to September, when it is about 20-88 in., the annual range of monthly mean pressure being thus only 0-20 in., so that the Pole may be said to be in a region of permanently high atmospheric pressure. Cyclonic depressions crossed the region of the "Fram" with considerable frequency, 73 being experienced in the three years, the frequency being greatest in winter but the wind velocity in cyclones greatest in summer; the most constant movement of the wind was from west to east. The average velocity of the cyclonic winds encountered by the "Fram" was only about 29 m. per hour, the highest 40 m. per hour, the portion of the Arctic Sea she crossed being much less stormy than the coasts of the Arctic lands, where winds have been recorded of far greater severity, e.g. 45 m. per hour in Spitsbergen in 1882, 55 m. per hour in Teplitz Bay, Franz Josef Land, in 1900, 62 m. per hour on the Siberian coast in the "Vega" in 1879, and as much as 90 m. per hour at Karmakul in Novaya Zemlya in 1883. There seems little doubt that the interior of the polar area is a fair weather zone as compared with its margins, where the contrast of the seasons is more marked.

The land flora of the Arctic regions, although necessarily confined to the lower levels which are free from snow for some time every year, and greatly reduced in luxuriance and number of species as compared with the flora of the temperate zone, is still in its own way both rich and varied, and it extends to the most northerly land known. In some of the fjords of western Greenland and also of Ellesmere Land almost on the 86th parallel the prevailing colour of the landscape in summer is due to vegetation and not to rock. The plants which occur on the margin of the Arctic Sea and in the polar islands represent the hardier species of the North European, Asiatic and American flora, the total number of species amounting to probably about a thousand phanerogams and a still larger number of cryptogams. The habit of all is lowly, but some grasses grow to a height of 1 ft. 6 in., and the mosses, of which the Eriophyllum make their lamp-wicks, frequently form cushions more than a foot in depth. Trees are absent north of 73°N., which is the extreme point reached in Siberia, or they are dwarfed to the height of shrubs as in southern Greenland, or farther north to that of the prevailing herbage. The flowers of many Arctic species of phanerogams have an intensely brilliant colour. The plains and lower slopes of the plateaux of Ellesmere Land and Heiberg Land and the plain of Peary Land north of Greenland are sufficiently covered with vegetation to support large numbers of rodents and ruminants, the plants occurring not as occasional curiosities, but as the normal summer covering of the ground, playing their full part in the economy of nature. The cold of winter is not sufficient to put a stop to plant life even at the pole of cold in northern Siberia; and there is no reason to doubt that if there were islands close to the North Pole they would bear vegetation.

Fauna.—Animal life is comparatively abundant in the waters of the Arctic Sea, though the whalebone whale, Balaena mysticetus, has become almost extinct by reason of the energy with which its pursuit has been carried on. The white whale and narwhal still abound in the open waters as far north as ships can go. The walrus and several species of seal prey on the marine life, and the polar bear, the king of Arctic beasts, probably roams the whole surface of the frozen sea in pursuit of seals and the larger fish. The other Arctic carnivora include the Arctic fox and wolf, the latter attacking all the land mammals except the polar bear and old musk-oxen. The wild reindeer is still found in all the circumpolar lands except Franz Josef Land; but its range does not extend so far to the north as that of the typical ruminant of the polar lands, the musk-ox (Oreius moschatus), which now abounds only in Peary Land, north Greenland and in the American Arctic Archipelago, though it was formerly circumpolar in its distribution. The Arctic hare is almost equally characteristic and more abundant, and the lemming probably more common still. The ermine and other valuable fur-bearing animals also occur. The animals are either permanently white like the polar bear, or change their coats with the season, being brown in summer and white in winter like the hares and lemmings. The birds of the Arctic regions are all migrants, retreating southward in winter but nesting in incredible numbers on the Arctic coast lands, and in summer probably finding their way as individuals to every part. They are mainly sea-birds, though the snow bunting, the Arctic owl and other land birds are amongst the summer visitors. It is only in the case of the larger species of land birds that they can stand the extreme cold of Greenland and of many of the large islands are totally devoid of life of every kind on account of their unchanging covering of snow and the intensely rigorous climate due to their great altitude.

Arctic People.—The conditions of life in the continental parts of the Arctic regions are extremely severe as regards temperature in the winter, but it has been found possible for civilized people to live permanently both in the extreme north of North
America and in the north of Siberia. In the north of Norway where the winter is mild on account of the warm south-westerly winds from the open Atlantic, organized communities dwell within the Arctic Circle in free communication with the south by telegraph, telephone, steamer, and in some cases by rail also, all the year round. The climate on the coast of Norway is scarcely less favourable in the north than in the south except for the absence of light in winter when the sun never rises, and the absence of darkness in summer when the sun never sets. If there were natural products of sufficient value permanent settlements might arise in any part of the Arctic regions where there is land free from snow in summer; but as a rule Arctic land is poor in mineral wealth and the pursuit of whales and seals requires only a summer visit. The original people of the farthest north of Europe are now represented by the Lapps, who lead a migratory life, depending mainly on fishing and on their herds of reindeer. Farther east their place is taken by the Samoyed who live along the coast of the Kara Sea and the Yalynal Peninsula; they have also a small settlement in Novaya Zemlya. The Samoyedes, like the Lapps, live on the produce of the sea in summer and on their herds of reindeer, moving rapidly over the frozen country in winter by means of reindeer and sledges. The Chukchi and the Eskimo, who whom Franz Josef Land never had native inhabitants. Along the coast of Siberia there is no continuous population, except in the land of the Chukchis in the extreme east between the Kolyma river and Bering Strait; but small settlements of many tribes of pagan hyperboeans occur here and there. North American Indian tribes wander far to the north of the Arctic Circle in Canada and Alaska, keeping their hereditary enemies the Eskimo to the coast and islands. The Eskimo of the American coast are intermingling not only with the American whalers but also with the Polynesians who come north as part of the crew of the whalers, and the pure race is tending to disappear. The traces of Eskimo encampments in the Polar archipelago, where now no Eskimo now live, may mark a former wider range of hunting grounds, or a greater extension of the population. The Greenland Eskimo are the most typical and the best known of their race. A few hundred live on the east coast, where they were formerly much more numerous. The greater part of the west coast Eskimo are now civilized members of the Danish colonies, and it is stated that whereas in 1855 only about 30% of the population were half-breeds, the blending of the Eskimo and Europeans is now so complete that no full-blooded Eskimo remain in Danish Greenland. The tribe of Eskimo living to the north of Melville Bay, the natives of which are considered by the Danish of Denmark, Greenland, was first described by Sir John Ross, who called them Arctic Highlanders. They have been fully studied by Commander Peary, who succeeded in utilizing them in his great series of journeys, and to their aid he attributes the success of his method of Arctic travelling.

The Arctic Sea.

According to its geographical position, the Arctic Sea might be described as the sea situated north of the Arctic Circle; but according to its natural configuration, it is better defined as the gulf-like northern termination of the long and relatively narrow Arctic arm of the ocean which extends north between Europe and America on one side and America on the other. By this situation as the northern end of a long arm of the ocean its physical conditions are to a very great extent determined. This Arctic gulf is bounded by the northern coasts of Europe, Siberia, North America, the American Arctic archipelago, Greenland and Iceland. Its entrance is the opening between Europe and Labrador divided by Iceland, Greenland and the American Arctic islands; and its natural southern boundary would be the submarine ridge extending from Scotland and the Shetland Islands through the Faeroe Islands and Iceland to Greenland, and continuing on the other side of Greenland across Davis Strait to Baffin Land. This ridge separates the depression of the Arctic Sea, filled with cold water at the bottom, from the deep depression of the North Atlantic. The Arctic Sea communicates with the Pacific Ocean through Bering Strait, which is, however, only 49 m. broad and 27 fathoms deep. The area of the Arctic Sea may be estimated to be about 3,600,000 sq. m., of which nearly two-thirds (or 2,300,000 sq. m.) is continuously covered by floating ice.

The Arctic Sea may be divided into the following parts:

1. The North Polar Basin (including the Siberian Sea), bounded by the northern coasts of Siberia (from Bering Strait to the western Taimyr Peninsula), Franz Josef Land, Spitsbergen, Greenland, Grinnell Land, Axel Heiberg Land, Kings Land, the Parry Islands and Alaska;

2. The Kara Sea, between Novaya Zemlya and the Siberian coast, south of the point of the former to Lonely Island (Ensomschen) and Norden sköld Island;

3. The Barents and Murman Sea, bounded by Novaya Zemlya, Franz Josef Land, Spitsbergen, Bear Island and the northern coasts of Norway and Russia;

4. The Norwegian Sea, between Norway, Spitsbergen, Jan Mayen, Iceland and the Faeroes;

5. The Greenland Sea, between Spitsbergen, Jan Mayen, Iceland and Greenland;

6. Baffin Bay and Davis Strait, between Greenland, Ellesmere Land, North Devon and Baffin Land.

Depths.—The Arctic Sea forms an extended depression separating the two largest continental masses of the world—the European-Asiatic (Eurasia) and America. Along its centre this depression is deep, but around its whole margin, on both sides, it is unusually shallow—a shallow submarine plateau or drowned plain extending northward from both continents, forming the largest known continental shelf. North of Europe this shelf may be considered as reaching Spitsbergen and Franz Josef Land, extending over more than 10 degrees of latitude, although there is a somewhat deeper depression in between. North of Spitsbergen it reaches beyond 84° N., and north of Franz Josef Land probably somewhat north of 82° N. North of Siberia the shelf is 330 m. broad, or more, with depths of 50 to 80 fathoms, or less. In longitude 135° E. it reaches nearly 79° N., where the bottom suddenly sinks to form a deep sea with depths of 2000 fathoms or more. Farther east it probably has a similar northward extension. North of America and Greenland the shelf extends to about latitude 84° N. This shelf, or drowned plain, evidently marks an old extension of the continents, and its northern edge must be considered as the real margin of their masses, the coasts of which have probably been overflowed by the sea at some comparatively recent geological period. On this submarine plateau the Arctic lands are situated with seven islands to the north, Bear Island and Herschel Island to the south, Franz Josef Land, Novaya Zemlya, Lonely Island, the New Siberia Islands, Wrangel Island, the American Arctic archipelago. The depth of the shelf is, especially north of Siberia, very uniform, and usually not more than 50 to 80 fathoms. North of Europe it is intersected by a submarine fjord-like depression, or broad channel, extending eastward from the Norwegian Sea. Between Norway and Bear Island this depression is about 240 fathoms deep, and between Novaya Zemlya and Franz Josef Land 100 to 150 fathoms deep. It gives off several submerged fjords or channels towards the south-east into the shallow Murman Sea, e.g. one channel, more than 100 fathoms deep, along the Murman coast towards the entrance of the White Sea; another narrow channel, in parts 100 fathoms deep, along the south-west coast of Novaya Zemlya through Kara Strait. It also extends into the Kara Sea, rounding the north point of Novaya Zemlya and forming a narrow channel along its eastern coast. On the American side similar but much narrower submarine depressions, which may be called submarine fjords, extend from Baffin Bay into the continental shelf, northward through Smith Sound, Kane Basin and Kennedy Channel, and westward through Lancaster Sound.

The greatest depths in the Arctic Sea have been found in the North Polar Basin, where depths of 2100 fathoms, in about 81° N. and 135° E., have been measured with certainty. It is less than 180 fathoms along the whole course of the "Fram," from about 79° N. and 138° E. to near Spitsbergen. In 84° N. and about 75° E. the depth is 2020 fathoms,
and in 85° N. and 15° E. it is 1860 fathoms. The northern and eastern extension of this deep basin is not known. Commander Peary reports a depth of 1500 fathoms with no bottom at 5 sea miles from the Pole (about 80° 55' N.) where he tried to obtain a sounding. It was formerly believed that still greater depths existed west of Spitsbergen, in the so-called Swedish deep, where 2600 fathoms had been sounded, but the Nathorst expedition in 1808 found no greater depths there than about 1700 fathoms. The Norwegian Sea, farther south, is 2000 fathoms deep midway between Iceland and Norway, in about 68° N. This so-called Norwegian deep is, as before stated, separated from the North Atlantic Basin by the Wyville-Thomson ridge and the Faeroe-Iceland ridge. Farther north there is a low transverse ridge extending eastwards from Jan Mayen, in about 72° N., which is about 1300 fathoms deep. North of this the sea is again deeper—1085 fathoms in 75° N. From the north-west corner of Spitsbergen a submarine ridge extends in a north-westerly direction, with depths of about 430 fathoms in 81° N. and about 4° E. How far this ridge extends is unknown, but there is a probability that it reaches Greenland, and thus separates the Swedish and the Norwegian deep from the deep depression of the North Polar Basin. Baffin Bay forms, probably, a relatively deep basin of about 1000 or 1200 fathoms, which is separated from the West Atlantic Basin by the shallow submarine ridge from Greenland to Baffin Land in about 65° or 66° N.

The deposit composing the bottom of the Arctic Sea contains in its northern part, in the North Polar Basin, extremely little matter of organic origin. It is formed mainly of mineral material, sandy clay of very fine grain, to an extent which is hardly found in any other part of the ocean with similar depths. It contains only from 1 to 4% of carbonate of lime. Farther south, in the sea between Spitsbergen and Greenland, the amount of carbonate of lime gradually increases owing to the shells of foraminifera (especially bidulcinae); west of Spitsbergen the proportion rises to about 20 or even 30%, while in the direction of Greenland it is considerably lower.

The circulation of the Arctic Sea may be explained firstly by the vertical and horizontal distribution of temperature and salinity (i.e. density); secondly, by the influence of the winds, especially on the ice-covered surface. The currents in this sea may to some extent be considered as convection currents, caused by the cooling of the water near the surface, which becomes heavier, sinks, and must be replaced on the surface by warmer water coming from the south, which is also influenced by the prevailing winds. On account of the rotation of the earth the northward-running water on the surface, as well as the sinking water, will be driven in a north-easterly or easterly direction, and farther south the water runs along the bottom, as well as the rising water, is driven south-west or westward. This simple circulation, however, is to a great extent complicated on the one hand by the irregular configuration of the sea-bottom, especially the transverse submarine ridges—e.g. the Spitsbergen ridge, the Jan Mayen ridge, and the Scotland-Faeroe-Iceland ridge; and on the other hand by the circumstance that the upper water strata of the sea are comparatively light in spite of their low temperature. These strata, about 100 or 120 fathoms thick, are diluted by the addition of fresh water from the North European, Siberian, Canadian and Alaskan rivers, as well as by precipitation, while at the same time the evaporation from the surface of the mostly ice-covered sea is insignificant. The light surface strata will have a tendency to spread over the heavier water farther south, and thus the polar surface currents running southward along the east coasts of Greenland, Baffin Land and Labrador are formed, owing their westery course to the rotation of the earth. These currents are certainly to a great extent helped and increased by the prevailing winds of the region. The winds get a firm hold on the rough surface of the floating ice, which, with its deep hummocks and ridges, gets a good grip of the water, transferring the movement of the surface immediately down to at least 5 or 10 fathoms.

The chief currents running into the Arctic Sea are the following:—

1. The Gulf Stream, or Atlantic drift, passing north-eastward over the Scotland-Faeroe-Iceland ridge, along the west coast of Norway, with one branch running north-eastwards as far as Cape Farewell into the Barents Sea, and another branch running northwards along the margin of the shelf between Norway, Bear Island and Spitsbergen, passing as a very narrow current along the west coast of the latter, over the Spitsbergen ridge in the north-west corner, and into the North Polar Basin, where it flows gradually northward and eastward (on account of the rotation of the earth) below the cold but lighter layer, 100 fathoms thick, of polar water, and fills the North Sea basin below 100 or 120 fathoms to the bottom with Atlantic water.

2. The Illerminger Current, running north along the west coast of Iceland. One part of the water, running southwards in Danish Strait, following the Greenland Polar Current, whilst another smaller part runs northward, eastward and south-eastward to the north and east of Iceland.

3. The Atlantic current. Running northward along the west coast of Greenland, passes the ridge across Davis Strait, and flows into Baffin Bay, forming its deeper strata below the polar water in a similar way to the Gulf Stream in the North Polar Basin. There is a possibility that some slight portion of this current even reaches the latter along the bottom of the deep channel through Smith Sound.

4. A small current running northward into the North Polar Basin through Bering Strait.

The Arctic Sea receives also a contribution of fresh water from the rivers of northern Europe, Siberia and America, as well as from the glaciers of Greenland and the precipitation over the whole area of the sea itself.

The chief currents running out of the Arctic Sea are: (1) The Greenland Polar Current, running southward along the east coast of Greenland, and dividing itself into two branches, (a) the east Greenland branch, passing south through Denmark Strait and rounding Cape Farewell; (b) the east Iceland branch, running south-eastward between Iceland and Jan Mayen, towards the Faeroes. It seems as if only a small portion of this current actually passes the Faeroe-Iceland ridge and reaches the Atlantic Ocean. The greater part is partly mixed with the water of the Gulf Stream and is turned by the latter in a north-easterly direction, forming the kind of deep-water current in the northern part of the North Polar Sea. (2) The Labrador Polar Current, formed by the water running south through Smith Sound, Lancaster Sound and Jones Sound, as well as water from Baffin Bay, and also from the east Greenland current running Cape Farewell and crossing Davis Strait. (3) Along the south-east coast of Spitsbergen a polar current also passes in a south-westerly or westerly direction past South Cape, where it meets the Gulf Stream. (4) A small current probably also runs out along the western coast of Bering Strait.

Temperature and Salinity.—While the temperature is comparatively uniform, with small variations, the difference in salinity between the upper and lower strata is greater than in most other parts of the ocean. In the North Polar Basin the vertical distribution of temperature as well as salinity is very much the same in all places examined. Near the surface, from 0 down to 100 fathoms, the water is below the freezing point of fresh water (about 1° C.); in 200 fathoms it rises to about 0° C. (—1° C.). At a depth of about 250 fathoms—and is much diluted with fresh water (see above), the salinity gradually increasing downward from about 20 or 30 per mille near the surface to nearly 35 per mille in 100 fathoms. Below 100 fathoms the temperature as well as the salinity gradually increases, until they approach their maximum in about 160 or 200 fathoms, where the temperature varies between 32.5° (0.3° C.), north of the New Siberia Islands, and about 33° (1° C.) north of Franz Joseph Land; and the salinity is about 35.1 per mille. From this depth the temperature gradually sinks downward; 32° (0° C.) is found at about 490 fathoms in the western part of the basin—e.g. between about 84° N. 15° E. and 83° N. 56° E., while it is found in about 490 fathoms farther east—e.g. in 81° N. and 123° E. In depths between 1400 and 1600 fathoms the temperature has a second minimum between 30.6° (—0.8° C.) and 30.4° (—0.9° C.), below which depth the temperature again rises slowly, a few tenths of a degree towards the bottom. In all depths below 200 fathoms the salinity of the water remains very much the same, about 35.1 per mille, with very slight variations. This comparatively warm and saline water evidently originates from the branch of the Gulf Stream passing north across the submarine ridge from north-west Spitsbergen. The vertical distribution of temperature and salinity is very much the same,
summer and winter, throughout the North Polar Basin, except near the surface, which in summer is covered by a layer of fresh water arising from the melting of the snow-covered surface of the floe-ice. This fresh-water layer may attain a thickness of 5 or 6 ft. between the floes. North of the Siberian coast the sea is, during summer, covered with a layer of warm water from the Siberian rivers, and the temperature of the surface may rise to several degrees above freezing-point.

In the Norwegian and Greenland Seas there are greater variations of temperature. Below a certain limit, which in the northern part (on the eastern side) is about 350 fathoms deep, and in the southern part between 300 and 400 fathoms deep, this basin of the sea is filled with water which has an unusually uniform salinity of about 34.2 per mille, and the temperature of which is below zero centigrade, gradually sinking downward, from the above-mentioned limit, where it is 32° (0° C.); and down to 29°S (−1.2° C.) or 29°S (−1.3° C.) near the bottom in 1400 or 1600 fathoms. This cold underlying water of such a remarkably uniform and comparatively low salinity is formed chiefly in a small area between Jan Mayen and Spitsbergen, by the formation of ice and cooling down of the Atlantic surface water by radiation of heat during the winter. In this manner the surface water becomes heavier than the underlying water, and gradually sinks to the bottom. This water seems to be distinctly different from the hitherto known water filling the deep of the North Polar Basin, as it has a lower salinity and lower temperature; the known bottom temperature of the North Polar Basin being between 30°S (−0.7° C.) and 30°S (−0.6° C.), and the salinity about 35.1 per mille. This fact seems to indicate that there can be no direct communication between the deep depression of the North Polar Basin and the Norwegian-Greenland Sea, which are probably separated by a submarine ridge running from the north-west corner of Spitsbergen to Greenland.

The above-mentioned layer of uniform cold water of the Norwegian-Greenland Sea is, along its eastern side, covered by the warm and saline water of the Gulf Stream flowing northward along the west coast of Norway, Bear Island and Spitsbergen, and forming the upper strata of the sea about 300 to 500 fathoms deep. The maximum temperature of this water is on the surface about 46° (8° C.) to 50° (10° C.) west of northern Norway, and about 37° (5° C.) to 39° (4° C.) west of Spitsbergen. The salinity is generally between 35.0 and 35.3 per mille.

Along the western side of this sea, towards the east coast of Greenland, the underlying cold water is covered by the less saline water of the polar current, which, in the upper strata of the sea, from the surface down to about 100 fathoms, has very much the same temperature and salinity as in the upper cold and less saline strata of the North Polar Basin. Near the eastern coast of Greenland, a layer of comparatively warm and saline water, with a temperature of 32°S (−0.4° C.) and a salinity of 35.2 per mille, has been found (by the Ryder expedition in 1891) below the cold and lighter polar water in a depth of 70 to 90 fathoms. This warmer undercurrent is a continuation of the warm Spitsbergen current sending off a branch westward from Spitsbergen, and thus forming a great vortex movement in the Spitsbergen-Greenland Sea similar to the one mentioned farther south in the Norwegian Sea.

In Barents Sea the temperature and salinity are highest in the western part near Norway or between Norway and Bear Island, where the eastern branch of the Gulf Stream enters and where in summer the salinity generally is between 34.8 and 35 per mille from the surface down to the bottom, and the surface temperature generally is about 41° or 43° (5° C. or 6° C.), and the bottom temperature is above zero centigrade. The eastern part of Barents Sea is filled with water of a little lower salinity, the deeper strata of which are very cold, with temperature even as low as 28°S (−1.7° C.), but often with salinity above 35.0 per mille. This cold and saline water is formed during the formation of ice on the sea-surface. The bottom temperature is everywhere in the eastern part below zero centigrade and generally below −1° C.

The Kara Sea is covered near the surface with a layer of cold water much diluted by the fresh water from the Siberian rivers, especially the Ob and the Yenisei. The salinity varies between 29 and 34 per mille; near the mouth of the rivers it is naturally much lower.

The vertical distribution of temperature and salinity in Baffin Bay seems to be very similar to that of the North Polar Basin, with a cold but less saline upper stratum of water—with a minimum temperature of about 28°S (−1.7° C.)—and a warmer and more saline deeper stratum from 100 to 200 fathoms downwards, with a maximum temperature of 33°S (9° C.) in about 200 fathoms, and the temperature slowly decreasing towards the bottom.

Arctic Ice—As before mentioned, at least two-thirds of the Arctic Sea is constantly covered by drifting ice. This ice is mostly formed on the surface of the sea itself by freezing, the so-called floe-ice or sea-ice. A small part is also river-ice, formed on the rivers, especially those of Siberia, and carried into the sea during the spring or summer. Another comparatively small part of the ice originates from the glaciers of the Arctic lands. These pieces of glacier-ice or icebergs are, as a rule, easily distinguished from the floe-ice by their size and structure. They occur almost exclusively in the seas round Greenland, where they originate from the glaciers descending into the sea of the Greenland ice of Greenland. Some small icebergs are also formed in Franz Josef Land, Spitsbergen, Novaya Zemlya, Grinnell Land, &c., but they are comparatively insignificant, and are not as a rule carried far from the coasts. Sea-ice or floe-ice is formed during the autumn, winter, and spring, especially in the North Polar Basin, but also in the Kara Sea, the greater part of Barents Sea, the northernmost part of the Norwegian Sea (near Bear Island and towards Jan Mayen), Greenland Sea and Baffin Bay. The floe-ice does not, as a rule, grow thicker than 7 or 8 ft. in one year, but when it floats in the water for some years it may attain a thickness of 16 ft. or more directly by freezing. By the constant upheaval from pressure much greater thicknesses are attained in the piled-up hummocks and ridges, which may be 20 to 30 ft. high above the water when floating. During the summer the floe-ice decreases again by melting partly on the surface owing to the direct radiation of heat from the sun, partly on the under side owing to the higher temperature of the water in which it floats. The first kind of melting is that which prevails in the North Polar Basin, which the second occurs in more southern latitudes. The floe-ice is constantly more or less in movement, carried by winds and currents. The changing wind, and also to a great extent the changing tidal current, causes diverging movements in the ice by breaking it into larger or smaller floes. When the floes separate, lanes and channels are formed; when they meet, ice-pressures arise, and the floes are piled up to form hummocks or ridges, and thus the uneven polar ice arises. In the North Polar Basin the floe-ice is slowly carried by the prevailing winds and the currents in an average direction from Bering Strait and the New Siberian Islands, north of Franz Josef Land and Spitsbergen, near the North Pole, towards the Greenland Sea and southward along the east coast of Greenland. Such a drift of an ice-floe from the sea north of Bering Strait to the east coast of Greenland probably takes, as a rule, four or five years, and the floes found in this part of the sea are not, therefore, generally older. What the drift of the ice is on the American side of the North Polar Basin is still little known. But there it is probably more or less blocked up in its southward movement by the islands of the American Arctic archipelago, and the ice-floes may thus grow very old and thick. Commander Peary found a strong easterly movement of the floes in the region north of Grant Land in 1907. The southward distribution of the drifting floe-ice (the pack ice) in Barents Sea, Norwegian-Greenland Sea and Davis Strait may differ much from one year to another, and these variations are evidently due to more or less periodical variations in the currents and also in the directions of the prevailing winds. In most places the ice has its most southerly distribution during the late winter and spring, while the late summer and autumn (end of August and September) is the most open season.
Biological Conditions.—The development of organic life is comparatively poor in those parts of the Arctic Sea which are continuously covered by ice. This is, amongst other things, proved by the bottom deposits, which contain exceptionally little carbonate of lime of organic origin. The reason is evidently that the thick ice prevents to a great extent the development of plant life on the surface of the sea by absorbing the light; and as the plant life forms the base for the development of animal life, this has also very unfavourable conditions. The result is that—e.g. in the interior of the North Polar Basin—there is exceptionally little plant life in the sea under the ice-covering, and the animal life both near the surface and in deeper strata is very poor in individuals, while it is comparatively rich in species. Near the outskirts of the Arctic Sea, where the ice is more or less quitted during the greater part of the year, the pelagic plant life as well as animal life is unusually rich, and, especially during the early summer, there is often here such a development of plankton (i.e. pelagic life) on the sea-surface as is hardly found in any other part of the ocean. It seems as if the polar water is specially favourable for the development of pelagic plant life, which makes the flora, and consequently also the fauna, flourish as soon as the ice-covering disappears and the water surface is exposed to the full sunlight of the long Arctic day. At the same time the temperature of the water rises, and thus the conditions for the chemical changes of better and nutritive assimilation are much improved. The North Polar Basin, especially the North Polar Basin itself, may thus be considered as a lung or reservoir in the circulation of the ocean where the water produces very little life, and thus, as it were, gets time to rest and accumulate those substances necessary for organic life, which are everywhere present only in quite minimal quantities. It is also a remarkable fact of interest in this connexion that the greatest fisheries of the world seem to be limited to places where waters from the Arctic Ocean and from more southern seas meet—e.g. Newfoundland, Iceland, Lofoten and Finnmarken in Norway.

The mammalian life is also exceptionally rich in individuals along the outskirts of the Arctic Sea. We meet in those waters, especially along the margin of the drifting ice, enormous quantities of seals of various kinds, as well as whales, which live on the plankton and the fishes in the water. A similar development of mammalian life is not met with anywhere else in the ocean, except perhaps in the Antarctic Ocean and Bering Sea, where, however, similar conditions are present. In the interior of the Arctic Sea or the North Polar Basin mammalian life is very poor, and consists mostly of some straggling polar bears which probably occasionally wander everywhere over the whole expanse of ice; some seals, especially Phoca jona, which has been seen as far north as between 84° and 85° N.; and a few whales, especially the narwhal, which has been seen in about 85° N.

The bird life is also exceptionally rich on the outskirts of the Arctic Sea, and the coasts of most Arctic lands are every summer inhabited by millions of sea-birds, forming great colonies almost on every rock. These birds are also dependent for their living on the rich plankton of the surface of the sea. In the interior of the Arctic Sea the bird life is very poor, but straggling seabirds may probably be met with occasionally everywhere, during summer-time, over the whole North Polar Basin.

Antarctic Region

History of Antarctic Exploration.—Although the Antarctic region was not reached by the first explorer until the Arctic region had been for centuries a resort of adventurers in search of the route to the East, the discovery of the south polar region was really the more direct outcome of the main stream of geographical exploration. It was only early understood by the Greek geographers that the known world covered only a small portion of the northern hemisphere and that the whole southern hemisphere awaited exploration, with its torrid, temperate and frigid zones repeating the climatic regions familiar in the northern hemisphere, the habitable land of the south temperate zone being separated from the known world by the practically impassable belt of the torrid zone. During the middle ages the sphericity of the earth came to be viewed as contrary to Scripture and was generally disregarded, and it was not until Prince Henry the Navigator began in 1418 to encourage the penetration of the torrid zone in the effort to reach India by circumnavigating Africa that the exploration of the southern hemisphere began. The doubling of the Cape of Good Hope in
1487 by Bartholomew Diaz first brought explorers within touch of the Antarctic cold, and proved that the ocean separated Africa from any Antarctic land that might exist. The passage of Magellan's Strait in 1520 showed that America and Asia also were separated from the Antarctic continent, which was then believed to extend from Tierra del Fuego southward. The doubling of Cape Horn by Drake in 1578 proved that the Tierra del Fuego archipelago was of small extent and that any continent ever died a harder death. It is not to the purpose here to describe in detail how Schouten and Le Maire rediscovered the southern extremity of Tierra del Fuego and named Cape Horn in 1615, how Quiros in 1606 took possession for the king of Spain of all the lands he had discovered in Australia del Espiritu Santo (the New Hebrides) and those he would discover "even to the Pole," or how Tasman in 1642 showed that New Holland (Australia) was separated by sea from any continuous southern continent.

which lay to the south must be within the region of perpetual winter. Before this, however, vague reports of land to the south of the Malay archipelago had led European geographers to connect on their globes the coast of Tierra del Fuego with the coast of New Guinea, and allowing their imaginations to run riot in the vast unknown spaces of the south Atlantic, south Indian and Pacific oceans, they sketched the outlines of a vast continent stretching in parts into the tropics. The search for this great south land or Third World was a leading motive of explorers in the 16th and the early part of the 17th centuries, and no illusion Voyagers round the Horn frequently met with contrary winds and were driven southward into snowly skies and ice-encumbered seas; but so far as can be ascertained none of them before 1770 reached the Antarctic circle, or knew it, if they did. The story of the discovery of land in 64° S. by Dirk Gerritsen on board the “Blijde Boodschap” in 1599 has recently been shown to be the result of the mistake of a commentator, Kasper Barlaeus, in 1622. Much controversy has arisen as to whether South Georgia was sighted in 1575 by La Roche, but the point is of no importance in the development of the history of exploration. It may
safely be said that all the navigators who fell in with the southern ice up to 1750 did so by being driven off their course and not of set purpose. An exception may perhaps be made in favour of Halley's voyage in H.M.S. 'Paramour' for magnetic investigations in the South Atlantic, where he met the ice in 56° S. on January 31, 1717, but that latitude was his farthest south. A determined effort on the part of the French naval officer Pierre Bouvet to discover the South Land described by a half legendary sieur de Gonneville resulted only in the discovery of Bouvet Island in 54° 10' S., and in the navigation of 48 degrees of longitude of ice-encumbered sea nearly in 55° S. in 1739. In 1771 Yves Joseph Kerguelen sailed from France with instructions to proceed south from Mauritius in search of a "very large continent." He lighted upon a land in 58° S. which he called South France, and believed to be the central mass of the southern continent. He was sent out again to complete the exploration of the new land, and found to be only an ice-covered island which he re-named in disgust the Isle of Desolation, but in which posternity has recognized his courageous efforts by naming it Kerguelen Land. The obsession of the undiscovered continent culminated in the brain of Alexander Dalrymple, the brilliant and erratic hydrographer who was nominated by the Royal Society to command the Transit of Venus expedition to Tahiti in 1769, a post he coveted less for its astronomical interest than for the opportunity it would afford him of confirming the truthfulness of his favourite explorer Quiros. The command of the expedition was given by the admiralty to Captain James Cook, whose geographical researches were criticised by Dalrymple as a force and persistence which probably had some weight in deciding the admiralty to send Cook out again with explicit instructions to solve the problem of the southern continent.

Sailing in 1772 with the "Resolution," a vessel of 462 tons under his own command and the "Adventure" of 336 tons under James Cook, Captain Tobias Furneaux, Cook first searched in vain for Bouvet Island, then sailed for 20 degrees of longitude to the westward in latitude 58° S., and then 35° eastward for the most part south of 60° S. a higher southern latitude than had ever been voluntarily entered before by any vessel. On the 17th of January 1773 the Antarctic Circle was crossed for the first time in history and the two ships reached 67° 15' S. in 36° 35' E., where their course was stopped by ice. There Cook turned northward to look for South France, of the discovery of which he had received news at Cape Town, but from the rough determination of his longitude by Kerguelen, he assigned the longitude of his journey by Kerguelen, and continued to sail for 10° too far east and did not see it. He returned south and again stopped by ice in 62° 52' S. and 69° E. and continued eastward nearly on the parallel of 60° S. to 147° E. where on March 16th the approaching winter drove him northward for rest to New Zealand and the tropical islands of the Pacific. In November 1773 Cook left New Zealand, having parted company with Furneaux, and arrived at 60° S. in 17° 5' W., whence he sailed eastward keeping as far south as the floating ice allowed. The Antarctic Circle was crossed on the 20th of December and Cook remained south of it for three days, being compelled after reaching 67° 31' S. to stand north again in 125° W. A long detour to 47° 50' S. served to show that there was no land connexion between New Zealand and Tierra del Fuego, and turning south again Cook crossed the Antarctic Circle for the third time in 150° 30' W., and four days later his progress was blocked by ice in 71° 10' S., 106° 54' W. This point, reached on the 30th of January 1774, was the farthest south attained in the 18th century. With a great detour to the east almost to the coast of South America with a force and patience regained Tahiti for refreshment. In November 1774 Cook started from New Zealand and crossed the South Pacific without sighting land between 53° and 57° S. to Tierra del Fuego, then passing Cape Horn on the 29th of December he discovered the Isle of Georgia and Sandwich Land, the only ice-land he had seen, and crossed the South Atlantic to the Cape of Good Hope between 55° and 60° S., thereby wiping out Dalrymple's continent from all the oceans and lying open the way for future Antarctic discovery by exploiting the myth of a habitable southern continent. Cook's most southerly discovery of land lay on the temperate side of the 66th parallel, and he convinced himself that if land lay farther south it was practically inaccessible and of no economic value.

Cook's voyage in search of South Georgia both from England and America, but no clear accounts of the southern limits of their voyages before the year 1810 can now be obtained. In February of that year William Smith of the brig "Williams," trading between Monte Video and Valparaiso, rounding the Horn with a wide sweep to the south, saw land in 62° 40' S. Repeating the voyage in October he saw the land distinctly, and named it New South Shetland. The "Williams" was chartered by the British naval commander on the Pacific station, and in 1820 Edward Blanshard, master R.N., surveyed the group and went as far as 64° 35' among the islands. Meanwhile American sealers from Stonington, Connecticut, had begun operations on the newly discovered land, and one of these, Nathaniel B. Palmer, discovered the mountaneous archipelago still farther south which now bears his name. In 1821-1822 George Powell, apparently a British sealer, discovered and surveyed the South Orkney Islands which, though typical Antarctic lands, lie outside the Antarctic region.

A voyage only second in importance to that of Cook was planned in Russia and sent out by the emperor Alexander I. under the command of Fabian von Bellingshausen in the "Vostok," with Lieut. Lazareff in the "Mirni," in company, both vessels being about 500 tons. The object of the expedition was to supplement that of Cook by circum-navigating the Antarctic area, taking care to keep as far south as possible in those longitudes where Cook had made his northward detours. Bellingshausen entered on his exploring work by sighting South Georgia at the end of December 1819, discovered the Traverse Islands, sighted the Sandwich group and met a solid ice-pack in 60° S., to get round which he made a wide detour, sailing east to the south of Cook's track, and getting south of the 66th parallel in 8° W. On the 26th of January he crossed the Antarctic Circle in 8° W. and by February 1st had reached 69° 25'. in 1° 11'. a latitude which has never been surpassed on that meridian. Being stopped by ice, Bellingshausen turned northward and then continued to the east well to the south of Cook's track, getting south again as the ice permitted and reaching 69° 6'. in 18° E. On this occasion he was able to sail for three degrees of longitude within the circle before being forced north of it by a succession of heavy gales. He still kept eastward south of 65° S. and crossed the circle once more in 41° E., where the number of birds seen suggested the proximity of land, and in fact Enderby Land was not very far off, though out of sight. A storm of unexampled violence drove the ships northward, but they still held to the east south of 66° S. as far as 87° E., having followed the edge of the ice through those meridians south of the continent, and had made a great detour to the north. Bellingshausen now made for Sydney to rest and refit, arriving there on the 29th of March 1820, after 131 days under sail from his last port. At Sydney Bellingshausen heard of the discovery of the South Shetlands, and leaving early in November reached the sixth parallel a month later in longitude 143° W., and sailing eastward kept south of that parallel through 145 degrees of longitude during sixty-five days, never out of sight of the ice, keeping close along the pack edge through the great gap left by Cook south of New Zealand. He managed to cross the circle three times more, in 164° 30', in 120° W. and in 23° 30', where he reached 69° 52', the culminating point of the voyage. As the cruise was supplementary to Cook's, no attempt was made to get south of the meridian where that great navigator made his highest latitude. On the 22nd of January 1821, the day after reaching his highest latitude, Bellingshausen sighted the first land ever seen within the Antarctic Circle, the little island named after Peter I. A week later another and larger land, named after Alexander I., was seen at a distance of 40 m. and sketches made of its bold outline in which the black rock stood out in contrast to the snow.
Bellingshausen then made for the South Shetlands, where he met the American sealers, and thence returned to Russia. The voyage was a worthy pendant to that of Cook; it was carried out with a faithful devotion to instructions and consummate seamanship, and as a result it left only half the periphery of the Antarctic Circle within which land could possibly project beyond the Frigid Zone.

The next episode in the history of Antarctic exploration was the voyage of James Weddell, a retired master R.N., in 1823. Weddell was in command of the "Jane," a brig of 160 tons, with the cutter "Beaufort" of 65 tons in company, and after cruising among the South Orkneys during January he started for the south on exploration, and as he was well equipped with chronometers his positions may be taken as of a far higher degree of accuracy than those of ordinary sealers. On the 20th of February he reached the highest latitude yet attained, 74° 15' S. in 34° 17' W., having seen much ice but no impenetrable pack, and at the farthest point the sea was clear and open, but the lateness of the season and the length of the return voyage decided him to go no farther. Weddell made interesting collections of Antarctic animals, including the type specimen of the seal which bears his name, and the book in which he describes his voyage testifies to the keenness of his observations and the soundness of his reasoning. The sea which he penetrated so far to the south he named after the reigning king, George IV., but it is now known as Weddell Sea.

In 1829 Captain Henry Foster, R.N., in H.M.S. "Chanticleer" spent some months in the South Shetlands carrying on pendulum and gravity observations at the most southerly harbour that could be found, and though he did not go south of 65° 50' S. the careful observations which were made threw much light on the physical conditions of the Antarctic regions.

The firm of Enderby Brothers of London took a conspicuous part in the exploration of the Antarctic seas during the first four decades of the 19th century. They encouraged the masters of the whaling and sealing craft which they sent to the southern seas to take every opportunity that offered for exploration and to fix the position of any land seen with the greatest possible accuracy. The voyage of the Enderbys' brig "Tula," under the command of John Biscoe, R.N., with the cutter "Lively" in company, is worthy to rank with Cook's and Bellingshausen's expeditions, for it repeated and advanced upon their achievements with a mere fraction of their resources. The appearance of an iceberg which appeared to hold a mine of gold in its recesses, and Enderby's discoveries, was a keen explorer and a man given to thinking over and reasoning upon all that he saw, and in many of his conclusions he was far in advance of his time. At the beginning of January 1831 Biscoe, who had been hunting vainly for seals on the Sandwich group, started on a voyage easterly to look for new islands, and in trying to get south of 60° S. he had to coast the impenetrable ice-pack as far as 10° W., and continuing he got within the Antarctic Circle in 1° E. on a track parallel to that of Bellingshausen but farther east. Contrary winds delayed the little vessels; no seal-bearing lands were to be found, but in spite of difficulties, constant danger from fogs and icebergs, and disappointed crews, he held on eastward to the south of Cook's track, and, except at one or two points, to the south of Bellingshausen's also. Though his highest latitude was only 60° S. in 10° 43' E. on the 28th of January, he remained south of the Antarctic Circle, or within a few miles of it, for another month, when, in longitude 49° 18' E., he was rewarded by the discovery of land. But just as he was entering on a clear lead of water running straight for a promontory which he named Cape Ann, a terrific storm descended on the vessels, damaged them seriously and drove them helpless before it with the driving ice. A fortnight's struggle with the wind and ice brought Cape Ann into sight again on the 16th of March, but it was not to be conquered, the sea was beginning to freeze and half the crew were helpless with the effects of exposure, so Biscoe was compelled to give up the fight and reluctantly let the land—now known as Enderby Land—drop out of sight astern. With only three men able to stand, Biscoe brought the "Tula" into Hobart Town, Tasmania, and the "Lively," with only the master, one man, and a wounded boy alive, just escaped shipwreck in Port Philip Bay. After recruiting their health and completing their crews the two captains put to sea again and spent some time in sealing on the shores of New Zealand and neighbouring islands. They started south once more, and crossed 60° S. in 31° W. on the 28th of January 1832. Biscoe kept between 60° and the Antarctic Circle, north of Bellingshausen's route, for he dared not risk the lives of his second crew, but he got south to 67° S. in 75° W., and here, on the 14th of February, he again sighted land, which, in ignorance of Bellingshausen's discoveries in the same region, he believed was the most southerly land yet known. He named it Adelaide Land after the queen. A few days later he passed a row of low ice-covered islands—the Biscoe Islands—running from W.S.W. to E.N.E. Beyond these islands lay the mountains of an extensive land of which Biscoe took possession in the name of King William IV., and to which the name of Graham Land was subsequently given. Biscoe returned home after an arduous two months' sealing in the South Shetlands, and the splendid results of his relentless determination as an explorer won for him the gold medals of the young Geographical Societies of London and Paris.

In 1833 another of Enderby's captains named Kemp reported the discovery of land in 66° S. and 60° E. about 10° east of Enderby Land. The last of the great voyages of exploration due to Enderby Brothers was the cruise of the "Eliza Scott" under the command of John Balleny, with the cutter "Sabrina" in company. This voyage is interesting because it was the first attempted in high latitudes from east to west, and all those made in the opposite direction had suffered much from the buffeting of head winds. Balleny left Campbell Island south of New Zealand on the 17th of January 1839 and crossed the Antarctic Circle in 17° E. on the 20th. Heavy pack ice stopped him in 60° S., a higher latitude than had previously been reached in that region. On the 9th of February, after the little vessels had been working north-westward along the edge of the pack ice for more than a week, land was seen and found to be a group of mountainous islands—the Balleny Islands—one of which rose to a height of 12,000 ft., and another was an active volcano. Captain Freeman of the "Sabrina" made a momentary landing on one of the islands and was nearly drowned in the attempt, but secured a few bones of the seal, "Daceuta," as well as some bird skins. They were held on their way westward between latitudes 63° and 65° S., far south of any earlier voyager, and land, or an appearance of land, to which the name of the "Sabrina" was given, was reported in 121° E. In 103° 40' E. an iceberg was passed with a rock embedded in the ice, clear proof of land existing to the southward. A few days later the "Sabrina" was lost in a gale, but Balleny returned safely.

About 1835 the importance of obtaining magnetic observations in the far south, and the scientific interest of the study of the south polar regions led to plans being put forward for expeditions in the United States, France and Great Britain; in the first only; in the second and third, expeditions equipped to the frigates "Astrolabe" and "Zeéle" under Jules Dumont D'Urville for ethnographical research in the Pacific Islands, was instructed to make an attempt to surpass Weddell's latitude in the South Atlantic Ocean, and this D'Urville tried to do with conspicuous success, but for he never reached the Antarctic Circle though he spent the first two months of 1838 round the edge of the ice-pack south of the South Shetlands and the South Orkneys. Some portions of the land south of the South Shetlands were charted and named Juvillie Island and Louis Philippe Land; but the addition to knowledge was not great. Two years later, after fulfilling the main purpose of his expedition by collecting botanical and zoological specimens, D'Urville resolved for the glory of France to attempt to reach the Magnetic Pole, towards which he was aware that a British and an American expedition were directing their course. He left Hobart Town on the 1st of January 1840, and on the 20th he crossed the 66th parallel in 140° W. and discovered land 3000
or 4000 ft. high, which he named Adélie Land and took possession of by landing on a rocky islet off the icebound coast. Ten days later in 64° 30' S. D'Urville cruised westward along a high ice-barrier, which he believed to be connected with land, from longitude 131° E. and he named it the Clarie Coast. A few days later he left the Antarctic regions for the Pacific.

As early as 1836 the United States Congress had authorized an American Exploring Expedition in the programme of which Wilkes' Antarctic exploration had a leading place. Lient. Charles Wilkes was appointed to command the expedition of five vessels in August 1838, and his instructions, dated in that month, required him amongst other things to follow Weddell's route as far as possible, (2) to visit the most southerly point reached by Cook in the Antarctic, and (3) to make an "attempt to penetrate within the Antarctic region, south of Van Diemen's Land, and as far west as longitude 45° E., or to Enderby Land." The ships were in bad repair and ill-adapted for navigation in the ice, and many of the officers were not devoted to their chief; but in spite of great difficulties Wilkes fulfilled his programme. In following Weddell's route Wilkes in March 1839 fared no better than D'Urville in the previous year, but the "Flying Fish" of 66 tons under Lieutenant Walker reached 76° S. in 105° W., thus nearly reaching Cook's position of 1774. The third item of the Antarctic programme was made the subject of the most strenuous endeavour. Wilkes sailed from Sydney in the "Vincennes" on the 26th of December 1839, accompanied by the "Peacock" under Lient. William L. Hudson, the "Porpoise" under Lient. Cadwaladar Ringgold, and the "Flying Fish" under Lient. Finkney. They went south to the west of the Balleny Islands, which they did not see, and cruised westward along the ice-barrier or as near it as the ice-pack allowed towards Enderby Land nearly on the Antarctic Circle. The weather was bad with fogs, snowstorms and frequent gales, and although land was reported (by each of the vessels) at several points along the route, it was rarely seen distinctly and the chance of success was agreed among themselves in some cases. Unfortunate controversies have arisen at intervals during sixty years as to the reality of Wilkes' discoveries of land, and as to the justice of the claim he made to the discovery of the Antarctic continent. Some of the land claimed at the eastern end of his route has been shown by later expeditions not to exist; but there can be no doubt that Wilkes saw land along the line where Adélie Land, Kemp Land and Enderby Land are known to exist, even if the positions he assigns are not quite accurate. No one, however, could establish a claim to the discovery of a continent from sighting a discontinuous chain of high land along its coast, without making a landing. It seems no more than due to a gallant and much-persecuted officer, who did his best in most difficult circumstances, to leave the name of Wilkes Land on the map of the region he explored.

Unlike the other two expeditions, that equipped by the British government in 1847 was intended solely for Antarctic exploration and primarily for magnetic surveys in the south polar seas. There were two ships, the "Erebus" of 370 tons, and the "Erebus" of 340, stoutly built craft specially strengthened for navigation in the ice. Captain James Clark Ross, R.N., was in command of the "Erebus" and of the expedition; Commander Francis Rawdon Moira Crozier of the "Terror." A young surgeon, Joseph Dalton Hooker, joined the Royal Navy in order to go on the expedition, and he lived to take a keen interest in every subsequent Antarctic expedition down to that of Captain Scott in 1910. Ross had intended to make straight for the meridian of the Magnetic Pole, but, finding that D'Urville and Wilkes had already entered on those seas he determined to try to make a high latitude farther east, and leaving Hobart Town on the 12th of November 1840 he crossed the Antarctic Circle on the 1st of January 1841 and entered the pack ice on the 5th in 174° E. Instead of proving an impenetrable obstacle, the pack let the two ships work through in five days, and they emerged into open sea. Sailing towards the Magnetic Pole they found a chain of great mountains rising from a coast which ran due south from a prominent cape (Cape Adare) in 71° S. The continent was taken formal possession of for Queen Victoria by landing on Possession Island, the mainland being inaccessible, and the ships continued southward in sight of the coast of Victoria Land, where the loftiest mountain was named Mt Melbourne after the Prime Minister, until the twin volcanoes named Erebus and Terror were sighted in 78° S. on the 28th of January. From Cape Crozier, at the base of the mountains, a line of lofty cliffs of ice ran eastwards, the great ice-barrier, unlike any object in nature ever seen before, rising perpendicularly from the water to the height of 200 or 300 ft. and continuing unbroken for 250 m. Along this barrier the highest latitude of 78° 15' S. was attained, and the farthest point to the east was 167° W., while Ross turned to look for a winter harbour in Victoria Land. Being desirous to winter near the South Magnetic Pole, Ross did not explore McMurdo Bay between Mt Erebus and the north-running coast, where, as we now know, a harbour could have been found, and as he could not reach the land elsewhere on account of ice extending out from it for 15 or 16 m., after sighting the Balleny Islands at a great distance, on the 2nd of March the ships returned to Hobart. This was the most remarkable Antarctic voyage for striking discoveries ever made.

In November 1841 the "Erebus" and "Terror" returned to Antarctic waters, steering south-east from New Zealand and entering the ice-pack in about 60° S. and 146° W., the idea being to approach the great barrier from the eastward, but by the end of the year they had just struggled as far as the Antarctic Circle and they, together with the pack, were several times driven far to the northward by heavy gales in which the ships were at the mercy of the floating ice. During a storm of terrible severity on the 18th of January the rudders of both ships were smashed, and not until the 1st of February did they break out of the pack in 67° 25' S., 150° W. The barrier was sighted on the 22nd and the ships reached 78° 10' S. in 161° 27' W., the highest latitude attained for 62 years. To the eastward the barrier seemed impenetrable and extensive, but although Ross believed it to be land, he would only treat it officially as "an appearance of land," leaving the confirmation of its discovery as King Edward Land to the next century. No more work was done in this quarter; the "Erebus" and "Terror" turned the edge of the pack to the northward and on getting into clear water sailed eastward to Cape Horn, meeting the greatest danger of the whole cruise on the way by colliding with each other at night while passing between two icebergs in a gale.

After wintering in the Falkland Islands and making good the damage received, Ross made his third and last attack on the southern ice, and for six weeks he cruised amongst the pack between the south coast of the South Shetland Islands and a point of the South Pole 75° south by Ross's lat. line of 130° 15' meridian in 1842. He tried in vain to reach the Antarctic Circle. Failing in this attempt he turned to follow Weddell's route and skirted the pack eastward in 65° S., crossing Weddell's track on the 14th of February 1843, more than a degree farther south than D'Urville in his attempt four years before, but on the edge of an equally impenetrable pack. Coasting it eastward to 12° W. the "Erebus" and "Terror" at last rounded the pack and found the way open to the south, crossing the circle on the 1st of March. Four days later the pack was met with again and the ships were forced into it for 27 miles to latitude 71° 30' S. In 14° 51' W., nineteen degrees east of Weddell's farthest south. No sign of land was seen, a deep-sea sounding showed 4000 fathoms with no bottom, and although this was a mistake, for the real depth was later proved by Dr Bruce to be only 2660 fathoms, it showed at least that there was no land in the immediate neighbourhood.

This was Ross's last piece of Antarctic work, but the magnetic observations of his expedition were continued by Lient. T. E. L. Moore, R.N., in the hired barque "Pagoda," which left Simon's Bay in January 1845 and proceeded south-east, crossing the Antarctic Circle in 30° 45' E. and reaching a farthest south of 67° 30', nine degrees farther east. An attempt to reach Enderby Land was frustrated by the weather, and Moore continued his
voyage to Australia in a high latitude beating against contrary gales, a condition to which all previous experience pointed as likely to occur.

A second attempt at South Polar exploration was made for nearly thirty years, except a short cruise by Mr. Tapscott in the “Brisk,” one of Enderby’s ships which in February 1839, after passing the Balleny Islands, proceeded eastward to 145°E. at a higher latitude than Wilkes without sighting land. The first steamer to cross the Antarctic Circle was H.M.S. “Challenger,” on the 16th of February 1874; she only penetrated to 66° 40’S., in 78° 30’E., south of Kerguelen Land; but she continued her course to Australia for some distance in a high latitude, passing within 15 m. of the position assigned to Wilkes’s Termination Land without seeing any sign of land. Her dredgings and soundings yielded evidence as to the nature of the unknown region farther south. Sir John Murray believed that the soundings showed a general shoaling of the ocean towards the Antarctic ice, indicating the approach to a continent. By collecting and analysing all samples of deep-sea deposits which had been secured from the far south, he discovered a remarkable symmetry in the arrangement of the deposits. The globigerina ooze, or in deeper waters the red clay, carpeting the northern part of the Southern Oceans, merges on the southward into a great ring of diatom ooze, which gives place in turn, towards the ice, to a terrigenous blue mud. The fine rock particles of which the blue mud is composed are such as do not occur on oceanic islands, and the discovery of large blocks of sandstone dropped by icebergs proved the existence of sedimentary rocks within the Antarctic Circle.

During the southern summer in which the “Challenger” visited Antarctic waters, a German whale-ship, the “Grönland,” under Captain Dallmann, visited the western coast of the Antarctic Land south of Tierra del Fuego, and modified the chart in several particulars. The chief discovery was a channel, named Bismarck Strait, in 65°S., which seemed to run between Palmer Land and Graham Land.

When the International Circumpolar observations were set on foot in 1882, two scientific stations were maintained for a year in the southern hemisphere in order to obtain data for comparison with the observations at twelve stations round the North Pole. One of these was occupied by French observers in Tierra del Fuego in 55°S., the other by German observers at Royal Bay on South Georgia in 54°30’S. The magnetic and meteorological observations were of considerable importance.

In 1892 four steamers of the Dundee whaling fleet—the “Balena,” “Active,” “Diana” and “Polar Star”—went out to test Ross’s statement that the “right whale” inhabited Antarctic waters. The surgeons of two of the vessels—on the “Balena” Dr W. S. Bruce, on the “Active” Dr C. W. Donald—were selected for their scientific tastes, and equipped with all requisite instruments for observations and collecting. The result of the experiment was disappointing. No whales were obtained, and the ships devoted their attention to sealing on the east of Joinville Island and Louis Philippe Land, not going farther south than 65°S. (Geographical Journal, 1896, vii. 502–521, 625–643).

A Norwegian sealing, the “Jason,” Captain Larsen, also visited those seas in the same season, but the captain landed and collected fossils at several points north of 65°S. In 1893–1894 the “Jason,” accompanied by two other Norwegian vessels, the “Hertha” and the “Castor,” returned to the Antarctic and entered the ice-laden waters in November at the very beginning of summer. Captain Larsen in the “Jason” made his way as far south as 68°10’ in 66°W. on the eastern side of Graham Land, but several miles from the coast, which was bordered by a high ice-barrier. The land beyond this barrier was named Foyn Land, after a famous Norwegian whaling ship owner. Returning northwards, two small islands, Lindenberg and Christensen, were discovered and found to be active volcanoes. Meanwhile the “Hertha,” Captain Evensen, had reached the South Shetlands on the 1st of November 1893, and worked her way southward along the west side of Palmer Land and past the Biscoe Islands, reaching the Antarctic Circle on the 9th of November without meeting ice. This was the first time the Antarctic Circle had been crossed since the “Challenger” did so twenty years before.

A third attempt was made by the Norwegian whaling company, without encountering any trouble from ice-fogs he reached his farthest south, 66°10’S. in 66°12’W. (Mitteilungen der Geographischen Gesellschaft, Hamburg, 1895, pp. 245–294).

In 1894 the well-known Norwegian whaler, Svend Foyn, sent out one of his vessels, the “Antarctic,” Captain Christensen, to try his luck off the coast of Victoria Land. The “Antarctic” sailed from Melbourne in September 1894, having on board Carstens Egeberg Borchgrevink, a young Norwegian resident in Australia, who, being determined to take part in a voyage he could join in no other way, shipped as an ordinary seaman. He made notes of the voyage, and published an account of it on his return to Europe (Report of Sixth International Geographical Congress, London, 1895, pp. 169–175). The “Antarctic” entered in the pack in 62°45’S., 171°30’E., on the 8th of December 1894. The Balleny Islands were sighted on the 14th of December, and Cape Adare on Victoria Land two days later.

On the 22nd of January 1895 the farthest point was reached at Coulman Island in 74°S.; the sea was then easily navigable to the south. On the 23rd of January a small party, including the captain and Mr. Borchgrevink, landed on the mainland near Cape Adare, the first people to set foot on the Antarctic continent.

Efforts had been made from time to time, by Professor Georg von Neumayer in Germany and by Sir John Murray and others in Great Britain, to induce learned societies to inaugurate a new era of scientific Antarctic research on “Belgica,” under Government or at least under national auspices. In 1895 Sir Clements Markham, as president of the Royal Geographical Society and of the International Geographical Congress, also took the matter up, and interest in the Antarctic regions began to be aroused in every civilized country. Captain Adrien de Gerlache organized and led a Belgian expedition, for which he raised the funds with difficulty. M. Georges Lecomte, captain of the “Belgica,” and Lieut. Danco, magnetic observer, were Belgians; Mr. Roald Amundsen, the mate, a Norwegian; M. Arcowski, the geologist and physicist, a Pole; M. Racovita, the biologist, a Rumanian; and Dr. F. A. Cook, the surgeon, an American. On the 14th of January 1898, already long past midsummer, the “Belgica,” left Staten Island for Antarctic waters. She sighted the South Shetlands on the 21st and proceeded to Hughes Gulf, from which a channel, Gerlache Strait, was explored leading south-westward between continuous land, named Danco Land, on the east (the northern extension of Graham Land), and Palmer Land on the west. Palmer Land was found to be a group of large islands. On the 12th of February the “Belgica,” re-entered the open sea to the west at Cape Tuxen in 65°15’S. Much fog was experienced, but on the 16th Alexander Land was sighted in the distance. Continuing on a westerly course, the “Belgica” made every effort to enter the pack, which was successfully accomplished after a heavy storm on the 28th. By taking advantage of the leads, the expedition advanced to 71°30’S. in 85°15’W. by the 2nd of March, but the ship was blocked next day by the growth of young ice. Padding the pack into one continuous mass. For more than a year further independent movement was impossible; but the ship drifted with the ice between the limits of 80°30’W. and 102°10’W., and of 60°40’ and 71°35’S., which was the highest latitude attained (May 31, 1898). The sun set for seventy days, and all on board suffered severely from depression of spirits and disorders of the circulation, which Dr. Cook attributed to the darkness and to improper food. Lieut. Danco died during the period of darkness. On the 13th of March 1899, a second winter in the ice began to seem probable, the “Belgica” was released in 69°50’S. and 102°10’W. The geographical results of this expedition were insignificant so far as the discovery of land or penetration to a high latitude is concerned. The ship passed several times to the south and west of Peter I. Island, proving that the land seen by Belinghausen at that
POLAR REGIONS

point is of very limited extent. During the drift in the ice the soundings were usually between 200 and 300 fathoms, which, compared with the other depths (in the north) close to the continental shelf of considerable breadth, probably connected with land in the south. The scientific collections were of unique value and have been worked up and the results published at the expense of the Belgian government.

The Hamburg-America Company’s steamer “Valdivia,” chartered by the German Government for a scientific voyage “Valdivia,” under the leadership of Professor Carl Chun of Leipzig, with Dr Gerhard Schott as oceanographer, left Cape Town on the 13th of November 1841, and on the 25th was fortunate in rediscovering Bouvet Island (54° 26′ S., 3° 24′ E.), which had been searched for in vain by Cook, Ross, Moore and many other sailors. Steering south, the “Valdivia” although an unprotected steel vessel, followed the edge of the pack from 8° E. to 58° E., reaching 64° 15′ S. in 54° 20′ E. on the 16th of December. At this point a depth of 2541 fathoms was found, so that if Enderby Land occupies its assigned position, 102 nautical miles farther south, the sub-oceanic slope must be of quite unusual steepness. The rocks dredged up contained specimens of gneiss, granite and schist, and one great block of red sandstone weighing 5 cwt. was secured, confirming the theory of the continental nature of the land to the south.

On his return to England in 1895 Mr Borchgrevink made strenuous efforts to organize an Antarctic expedition under his own leadership, and in August 1896 he left the English Channel in the 130-ton steamer “Thames” as the “Southern Cross” in charge of a private expedition equipped by Sir George Newnes. His scientific staff included Lieut. Colbeck, R.N.R.; Mr Louis Bernacchi, a trained magnetic observer, and Mr N. Hanson, biologist. About fifty dogs were taken out, the intention being to land at Cape Adare and advance towards the magnetic, and perhaps also towards the geographical pole by sledge. The “Southern Cross” sighted one of the Balleny Islands on the 14th of January 1899, and after in vain attempting to get south about the meridian of 164° E., the ship forced her way eastward and emerged from the pack (after having been beset for forty-eight days) in 76° S., 174° E. She reached Cape Adare, and anchored in Robertson Bay on the 17th of February. The land party, consisting of ten men, was established in a house built on the strip of the beach at the base of the steep ascent to the mountains, and the ship left on the 2nd of March. Mr Borchgrevink found it impossible to make any land journey of importance and the party spent the first year ever passed by man on Antarctic land in making natural history collections and keeping up meteorological and magnetic observations. The “Southern Cross” returned to Cape Adare on the 28th of January 1900, and after taking the winter party on board—diminished by the death of Mr Hanson—set out for the south on the 2nd of February. Landings were made on several islands, on the mainland at the base of Mt Melbourne, and on the 10th of February at the base of Mt Terror, near Cape Crozier. From this point the ship steamed eastward along the great ice-barrier to a point in 164° 10′ W., where an inlet in the ice was found and the ship reached her highest latitude, 78° 34′ S., on the 17th of February. The edge of the ice was found to be about 30 m. farther south than it had been when Ross visited it in 1842. Mr Borchgrevink was able to land on the ice with sledges and dogs, and advanced southward about 16 m., reaching 78° 50′ S. He discovered that plant life existed in the shape of mosses and lichens in some of the rocky islands, a fact not previously known.

In the autumn of 1901 three well-equipped expeditions left Europe for Antarctic exploration. The British Antarctic expedition organized by the Royal Society and the Royal Geographical Society, and equipped under the superintendence of Sir Clements Markham. Most of the cost was borne by the government, the rest mainly by Mr L. W. Longstaff, who provided £39,000, the Royal Geographical Society, and Mr A. C. Harmsworth (afterwards Lord Northcliffe). A strong wooden ship of about 700 tons register (1700 tons displacement) was built at Dundee, and named the “Discovery.”

She was made entirely non-magnetic amidships, so that magnetic observations might be carried on without interference. The expedition sailed under the command of Commander R. F. Scott, R.N., with Lieut. Albert Armitage, R.N.R., as second in command, Lieuts. Royds and Barne, R.N., Lieut. Shackleton, R.N.R., and Engineer-Lieut. Skelton, R.N. The crew of forty men were almost entirely sailors of the Royal Navy. The scientific staff included Dr Koettlitz, who had shared with Mr Armitage in the Jackson-Harmsworth Arctic expedition; Mr Louis Bernacchi, who had wintered with Mr Borchgrevink at Cape Adare; Dr E. A. Wilson, Mr Hodgson, biologist, and Mr Ferrar, geologist. The “Discovery” sailed from New Zealand on the 24th of December 1901, met the pack ice on the Antarctic circle and was through it into the open sea in 175° E. on the 8th of January 1902. She made a quick run to Cape Crozier and cruised along the great ice barrier, confirming Borchgrevink’s discovery that it lay 30 m. farther south than in 1812, and at the eastern end of the barrier Scott discovered and named King Edward Land where Ross had recorded an “appearance” only. The sea in the neighbourhood had shoaled to less than 200 fathoms and the ice-barrier in places was so low that the “Discovery” was able to lie alongside as at a quay. A captive balloon ascent was made from the barrier but nothing was seen to the south. Returning to McMurdo Bay the “Discovery” found that Mr Erebis and Terror were on an island, the “bay” being only a sound. The ship was secured in winter quarters in 77° 49′ S. 160° E., and a hut erected on shore. From this base land-exploration in the Antarctic was initiated, and the history of exploration entered on a new phase. Although some symptoms of scurvy appeared during the winter they were checked by change of diet, and with the beginning of spring sledge journeys with dogs were commenced and a quantity of provisions was laid down in depots to assist the great journey which Scott had planned to the south. On the 2nd of November 1902 Captain Scott, with Lieut. E. H. Shackleton and Dr E. A. Wilson, set out with dog-sledges travelling south over the surface of the barrier in sight of a range of new mountains running parallel to their track on the west. The conditions of travelling were unlike those in the Arctic region, the weather being more inclement and the summer temperature much lower than in similar latitudes in the north. There were no bears to menace the safety of the travelling, and no wolves or foxes to plunder the depots; but on the other hand there was no game of any sort to be met with, and all food for men and dogs had to be carried on the sledges. The surface of the ice was often rough and much crevassed, especially near the western land, snow blizzards frequently occurred making travelling impossible and the heavy sledges had at first to be brought forward by relays, making it necessary to march three miles for every mile of southward made. The dogs also weakened and had to be killed one by one to feed the rest. On the 30th of December they were in 85° 17′ S. and Scott determined to try to reach the mountains to the west; but on approaching the land he found the ice so much crevassed and disturbed that the attempt had to be given up. Great peaks in 83° S. were named Mt Markham (15,100 ft.) and Mt Longstaff (1700 ft.) after the chief promoters of the expedition. The outward journey of 380 m. had taken 59 days, and was a splendid achievement, for the conditions to be encountered were totally unknown, and new methods had to be devised as the necessity arose, yet no previous polar explorer had ever advanced so far beyond his predecessor as Scott did. The return journey occupied 34 days and the ship was reached on the 3rd of February 1903, but Shackleton had been driven down into the pack ice, where he perished. The “Endurance” sank on the 3rd of March, Lieut. Shackleton, R.N., being taken to the coast by the “Discovery.” The absence of the commander in the great southern journey Armitage and Skelton had found a way to ascend by a glacier in 78° S. to the summit of the vast snow-covered plateau beyond the granite summits of the western mountains. They reached a distance of 130 m. from the ship and an elevation of 9000 ft. Many shorter journeys were made; Ferrar studied the geology of the
mountains and Hodgson was indefatigable in collecting marine fauna, while Bernacchi kept up the physical and meteorological observations. The second winter was lightened by the use of acetylene gas for the first time, and the dark months were passed in better spirits and better health than in the case of any previous polar wintering. In the spring of 1903-1904 Scott undertook a great journey on the western plateau, starting on the 26th of October without dogs. By the 30th of November he had reached a point on the featureless plateau of dead-level snow, 309 m. due west from the ship, the position being 77° 59' S., 146° 33' E. and 9000 ft. above sea-level. The ship was reached again on the 25th of December, and on the 4th of January the "Morning" arrived accompanied by a large vessel, the "Terra Nova," sent out by the Admiralty with orders to Captain Scott to abandon the "Discovery" and return at once. Fortunately, although all the stores and collections had been transferred to the relief ships, the "Discovery" broke out of the ice on the 16th of February 1904 and Captain Scott had the satisfaction of bringing her home in perfect order. The relief ships had provided so little coal that a most promising voyage to the westward of the Balleny Islands had to be abandoned in 135° E.; but it showed that the land charted by Wilkes east of that meridian did not exist in the latitude assigned.

Simultaneously with the "Discovery" expedition and in full co-operation with it as regards simultaneous meteorological and magnetic observations, the German government, "Gauss," equipped an expedition in the "Gauss" which was specially built for the occasion. The expedition was under the charge of Professor Erich von Drygalski and the scientific staff included Professor Vanhöfen as naturalist, Dr Emil Philippi as geologist and Dr Friedrich Biddingmaier as meteorologist and magnetician. The ship was under the command of Captain Hans Ruser of the Hamburg-American line. A supplementary expedition set up a station for simultaneous observations on Kerguelen Land. The "Gauss" crossed the parallel of 60° S. in 92° E. early in February 1902 and got within 60 m. of the charted position of Wilkes' Termination Land, where a depth of 1730 fathoms was found with no sign of land. The pack made it necessary to turn south-westward and land was seen to the eastward on February 1902 on the Antarctic Circle in the direction of Termination Land. Soon afterwards the "Gauss" was beset and spent the winter in the ice. Land of considerable extent was seen to the south and was named Kaiser Wilhelm II. Land; the most conspicuous feature on it was a hill of bare black rock with an elevation of about 1000 ft., which was called the Gaussberg, and was situated in 67° S., 90° E. This was the only bare land seen, and its neighbourhood was thoroughly investigated by a party led by the energetic landlubber Bernhard Borchardt. In February 1903 the "Gauss" was freed from the ice; but although Drygalski struggled for two months to thread the maze of fies to the eastward and south he could gain no higher latitude and was able to force his way only to 80° E. before seeking the open sea. The scientific observations and collections were most extensive and of great value.

Two private expeditions organized by men of science were in the Antarctic region simultaneously with the British and German national expeditions, and the synchronous meteorological and magnetic observations added to the value of the scientific results of all the parties. Dr. Otto Nordenskjöld, nephew of the discoverer of the North-East Passage, led a Swedish party in the "Antarctic," with Captain C. A. Larsen in command of the ship, and reached the South Shetlands in January 1902, afterwards exploring on the east side of Joinville Island and Louis Philippe Land, and wintering on shore on Snow Hill Island in 64° 25' S. From this point a long journey on ski over the flat sea ice bordering King Oscar Land was made to the south, but the Antarctic Circle was not reached. Meanwhile the "Antarctic" had succeeded in penetrating the pack in the Weddell Sea almost to the circle in 56° W., where D'Urville and Ross had failed to get so far south. A second winter was spent at the base on Snow Hill Island, and, the ship having been lost in the ice on her way to take them off, the party was rescued by a brilliant dash of the Argentine gunboat "Uruguay," under Captain Irizar, before the relief ship sent from Sweden arrived.

Meanwhile Dr W. S. Bruce, largely aided financially by Mr James Coats and Captain Andrew Coats, equipped a Scottish expedition in the "Scotia," with Captain Bruce.

Bruce, Alexander Thomason in command of the ship, and a scientific staff including Mr K. C. Mossman as meteorologist, Mr K. N. Rudmose Brown as naturalist, and Dr J. H. H. Pirie as geologist. The principal object of the expedition was the exploration of the Weddell Sea. The "Scotia" sighted the Orkneys on the 3rd of February 1903, and after a short struggle with the pack she found an open sea at 70° 25' S., where she was beset on the 22nd in 18° W., and whence she returned by a more westerly course, crossing the Antarctic Circle in 40° W. This important voyage midway between the tracks of Weddell and Ross, who alone of all who tried had reached 70° S. in this region, practically demonstrated the navigability of Weddell Sea in favourable conditions, and the oceanographical observations made were the most valuable yet carried out in the Antarctic region. The following year, starting from the Sandwich group Bruce crossed the Antarctic Circle about 29° W., and was able to make a straight run south to 74° 1' S., where the "Scutia" was stopped by the ice in 159 fathoms of water, the ship having sheared rapidly from a great depth. From the 3rd of March to the 15th the "Scotia" remained in shallow water, catching occasional glimpses of a great ice wall with snow-covered heights beyond it, along a line of 150 m., and dredging quantities of continental rocks. On this evidence the name Coats Land was given to the land within the barrier. The "Scotia" crossed the Antarctic Circle northward in 118° W., having in the two years explored a totally unknown sea for a distance of thirty degrees of longitude. A meteorological station was established by Mr Mossman in Laurie Island, in the South Orkneys (61° S.) in March 1903, and kept up by him for two years, when it was taken over by the Argentine government, and it now has the distinction of being the most southerly station at which continuous observations have ever been taken for over five years.

In January 1904 Dr Jean B. Charcot, a man of science and an accomplished yachtsman, left the French archipelago for the Antarctic in the "Français," in command of a French exploring expedition equipped at his own instance. He cruised through the islands of the Palmer Archipelago, and wintered in a cove of Wandel Island 65° 5' S. near the southern entrance of Gerlache Strait. On the 27th of December 1904 the "Français" was free, and continued to cruise southward along the coast of Graham Land, to the south of which, on the 15th of January, when nearly in latitude 67°, a new coast appeared, mountainous and stretching to the south-west, but Charcot could not determine whether it was joined to Graham Land or to Alexander Land. While approaching the land the "Français" struck a rock, and was so much damaged that further exploration was impossible, and after naming the new discovery Loubet Land, the expedition returned. Charcot organized a second expedition in 1908 on board the "Pourquoi Pas?" and, leaving Punta Arenas in December, returned to the Palmer Archipelago, and during January 1909 made a detailed examination of the coast to the southward, finding that Loubet Land was practically continuous on the north with Graham Land and on the south with Alexander Land, which was approached within a mile at one point. Adelaide Island, reported by Bischoe as 8 m. long, was found to be a large island 70 m. in length, consisting of a series of summits rising out of an icefield. The Bischoe Islands were found to be much more numerous than was formerly supposed. The expedition wintered at Petermann Island in 65° 10' S., and attempts were made to reach the interior of Graham Land, though with little success. After ceasing from the whalers' dépôt at Deception
Island, the "Pourquoi Pas?" sailed on the 6th of January 1910 to the south-west, and reached 70° S. on the 11th, whence views of Alexander Land were obtained from a new position, and a new land discovered farther to the south-west. The highest latitude reached was about 76° 30' S., and Charcot was able to divide his party into two parallel columns, one of which passed the region of the "Belgica's" drift, passing close to Peter I. Island across the meridian of Cook's highest latitude, where the ice seemed to promise an easy way south if coal had permitted, and on to 128° W. through an absolutely unknown sea, from which point a direct course was made for Punta Arenas. Frequent soundings and dredgings were made, and Dr Charcot satisfied himself from all the appearances that along the 20 degrees of longitude west of Gerlache's farthest, and more than half-way from Graham Land to King Edward Land, land was probably not far distant to the south.

After his return invalided from the "Discovery," Lieut. Shackleton planned a fresh expedition, which he equipped at his own expense, aided by his personal friends, and which he started in the small whaler "Nimrod" from Lyttelton, New Zealand, on the 1st of January 1908, being towed by a steamer to the Antarctic Circle, in order to save coal. The plan was to land a shore party on King Edward Land and return to take them off in the following year, but although a strenuous effort was made to reach the land the floe ice was too heavy, and it would have been madness to establish winter-quarters on the barrier, the coast-line of which had altered greatly since 1902, and was obviously liable to break off in great ice-lands. On the 26th of January the "Nimrod" began to return from the extreme east of the barrier, and the landing of stores commenced on the 3rd of February at Cape Royds, at the base of Mt Erebos, 20 m. north of the "Discovery's" winter-quarters. The shore party included the leader and fifteen companions, amongst them Professor T. W. Edgeworth David, of Sydney University; Lieut. Jameson Boyd Adams, R.N.R.; Sir Philip Brocklehurst, Bart.; Mr James Murray, biologist; Mr Raymond E. Priestley, geologist; Dr Alistair Forbes Mackay; Dr Eric Marshall; Mr Douglas Mawson, geologist; and Ernest Joyce and Frank Wild of the Royal Navy, who had taken part in the "Discovery" expedition. No casualty occurred during the whole duration of the expedition, special care having been taken to supply the best provisions, including fresh bread baked daily and dried milk in unlimited quantity, while abundant artificial light was secured by the use of acetylene gas. A motor-car was taken in the hope that it might be used on the barrier surface, but this was found impracticable, although it did good work in laying dépôts on the sea-ice. Another and more successful experiment in traction was the use of Manchurian ponies. Eight of these extraordinarily hardy creatures were taken south in the "Nimrod," but four died in the first month after landing. The others did good service. Nine dogs were also taken, but the experience on the "Discovery" expedition did not lead to much dependence being placed on them. The "Nimrod" left for the north on the 22nd of February and the scientific staff at once began the observations and collections which were kept up to the end. The discovery of a considerable fresh-water fauna and of a poor but characteristic flora was one of the most unexpected results. Apart from many minor excursions and surveys, the expedition performed three journeys of the first importance, each of them surpassing any previous land work in the Antarctic regions.

Before winter set in, Professor David, with five companions, made the ascent of Mt Erebos, starting from the winter quarters the 4th of March, and gaining the summit at an altitude of 13,300 ft. on the 10th; this was found to be the edge of an active crater, the abyss within being 900 ft. deep, though rarely visible on account of the steam and vapours which rose in a huge cloud 1000 ft. above the summit.

The second achievement was the attainment of the South Magnetic Pole by Professor David, with Mr Douglas Mawson and Dr Mackay. They left winter-quarters on the 6th of October 1908, dragging two sledges over the sea-ice. Proceeding along the coast they were able to supplement their provisions and fuel by seal-meat and blubber, and on the 1st of December they reached the Drygalski ice barrier in 75° S., which proved very difficult to cross. Leaving this ice barrier on the 16th, they proceeded to ascend the plateau with only sledges, and notes on the great risks from the crevasses into which they were constantly falling. On reaching the summit of the plateau travelling became easier, and on the 16th of January the magnetic dip was 90°, and the position of the magnetic pole was determined as 78° 25' S., 153° 10' E., at an altitude of 7260 ft. and 260 m. from the dépôt of provisions left at the Drygalski glacier. The return journey to this point was accomplished by forced marches on the 3rd of February, and next day the party was picked up by the "Nimrod," which was scouting for them along the coast.

The third and greatest achievement of this remarkable expedition was Shackleton's great southern journey. Dépôts had been laid out in advance on the barrier ice, and the main southern party, consisting of Messrs Shackleton, Adams, Marshall and Wild, started from winter-quarters on the 29th of October 1908, with the four ponies and four 11-ft. sledges; a supporting party of five men accompanied the main division for ten days. In order to avoid the disturbed and crevassed ice near the great south-running mountain range, Shackleton kept about 40 m. farther to the east than Scott had done. The ponies enabled rapid progress to be made, but after passing the 81st parallel on the 21st of November, one pony broke down and had to be shot, the meat being left in a dépôt for the return journey. In spite of cold weather and frequent high winds, progress was made at the rate of 15 m. per day, and on the 26th of November the farthest south of the "Discovery" expedition was passed, and Mts Markham and Longstaff were in full view. New mountains continued to appear beyond these, and the range changed its southerly to a south-easterly trend, so that the path to the Pole lay through the mountains. On the 28th a second pony became used up and was shot, and a dépôt was formed with provisions and stores for the return in 81° 38' S., and progress was resumed with two sledges. The surface of the barrier ice formed great undulations of gentle slope. On the 1st of December a third pony had to be shot, in 82° 16' S., and borselphone became the principal article of diet; the remaining pony hauled one sledge, the four men took the other. On the 4th of December the party left the barrier, passing over a zone of much disturbed ice, and commenced the ascent of a great glacier (the Beardmore glacier) which descended from the mountains between magnificent granite cliffs 2000 ft. high. On the 7th, when toiling amongst a maze of crevasses on the glacier, 2000 ft. above sea-level, the last pony fell into a crevasse and was lost, though the loaded sledge was saved; the pony was to have been shot that night as it could not work on the disturbed ice; but its loss meant so much less food, and as far as can be judged this alone made it impossible for the party to reach the Pole. For the next few days of laborious advance one or other of the party was continually falling into a crevasse, but the sledge harness saved them, and no serious harm resulted. After climbing upwards for 100 m. on the glacier, a dépôt was made at a height of 6000 ft. of everything that could possibly be left behind, including all the warm clothing, for it was found possible with Jaegers and wind-proof Burberrys to meet any weather in which exertion was possible. By Christmas Day the plateau surface was fairly reached at a level of 9500 ft., in latitude 83° 55' S., and there was no more difficulty to overcome. The party landed, and merely the effort of going on over a nearly level surface with insufficient food in a very low temperature, intensified by frequent blizzards. Rations were reduced in the hope of being able to push on to the Pole. Three days later the last crevasse was passed and the surface, now 12,200 ft. above sea-level, grew smoother, allowing 15 m. a day to be done with fair weather. At 4 a.m. on the 9th of January 1909 the four explorers left their sledge and
racing, half walking, half running, they reached 88° 25′ S. in 109° E. at 9 a.m., the height above sea being 11,600 ft. The utmost had been done, though more food would have enabled the 97 geographical miles to the South Pole to be accomplished. The camp was reached again at 3 p.m. The return journey of over 700 m. to the ship was one long nightmare of toil and suffering, but the length of the marches was unsurpassed in polar travel. Once and again all food was exhausted the day before the dépot, on which only hope of life depended, was picked up in the waste of snow. Snow-blindness and dysentery made life almost unendurable; but, despite it all, the ship was reached on the 1st of March, and the geological specimens from the southernmost mountains, which prevented the sledges of the exhausted men being lightened as they went on, were safely secured. Never in the history of polar exploration had any traveller outdistanced his predecessor by so vast a step towards either Pole.

During the return journey of the "Nimrod" Shackleton was able to do a little piece of exploration to the south of the Balleny Islands, tracing the coast of the mainland for 50 m. to the south-west beyond Cape North, thus indicating that the Antarctic continent has not a straight coast-line running from Cape Adare to Wilkes Land. The British government contributed £20,000 to the expenses of the expedition in recognition of the great results obtained, and the king conferred a knighthood on the explorer, the first given for Antarctic exploration since the time of Sir James Clark Ross.

Captain R. F. Scott left England in the summer of 1910 with a new expedition in the "Terra Nova," promoted by his own exertions, aided by a government grant, and with a carefully selected crew and a highly competent scientific staff. He intended to arrange for two parties, one leaving King Edward Land, the other McMurdo Sound, to converge on the South Pole. A German expedition under Lüt. Wilhelm Filchner was announced to leave early in 1911 with the hope of exploring inland from a base in the western part of Weddell Sea, and Dr W. S. Bruce has announced for the same year an expedition to the eastern part of Weddell Sea mainly for oceanographical exploration. It appears that the greatest extension of knowledge would now be obtained by a single attempt to cruise round the southpolar area from east to west in the highest latitude which can be reached. This has never been attempted, and a modern Biscoe with steam power could not fail to make important discoveries on a westward circumnavigation.

Physiography of Antarctic Region.—In contrast to the Arctic region, the Antarctic is essentially a land area. It is almost certain that the South Pole lies on a great plateau, part of a land that must be larger and loftier than Greenland, and may probably be as large as Australia. This land area may be composed of two main masses, or of one continent and a great archipelago, but it can no longer be doubted that the whole is of continental character as regards its rocks, and that it is permanently massed into one surface with ice and snow, which in some parts at least unites lands separated by hundreds of miles of sea. But all round the land-mass there is a ring of deep ocean cutting off the Antarctic region from all other land of the earth and setting it apart as a region by itself, more unlike the rest of the world than any continent or island. The expedition of the "Scottia" showed the great depth of the Weddell Sea area, and the attention paid to soundings on other expeditions—notably that of the "Belgica"—has defined the beginning of a continental shelf which cannot be doubted slopes up to land not yet sighted.

In the Arctic region large areas within the Polar Circle belong to climatically temperate Europe, and to habitable lands of Asia and America; but in the Antarctic region extensive lands—Graham Land, Louis Philippe Land, Joinville Island and the Palmer archipelago outside the Polar Circle—partake of the typically polar character of the higher latitudes, and even the islands on the warmer side of the sixthieth parallel are of a sub-Antarctic nature, akin rather to lands of the frigid than to those of the temperate zone.

Geology.—Definite information as to the geology of Antarctic land is available from three areas—Graham Land and the archipelago to the north of it, Kaiser Wilhelm Land and Victoria Land. In the Graham Land region there seems to be a fundamental rock closely resembling the Archæan. Palæozoic rocks have not been discovered so far in this region, although a gryptolite fossil, probably of Ordovician age, shows that they occur in the South Orkneys. Mesozoic rocks have been found in various parts of the archipelago, a very rich Jurassic fossil flora of ferns, conifers and cycads having been studied by Nordenskjöld, some of the genera found being represented also in the rocks of South America, South Africa, India and Australia. Cretaceous ammonites have also been found, and Tertiary fossils, both of land and of marine forms, bring the geological record down probably to Miocene times, the frola in the rocks of the south-west part of Niue Island. beaches show an emergence of the land in Quaternary times, and there is evidence of a recent glacial period when the inland ice on Graham Land was a thousand feet higher than it is now. The most prominent features of the scenery are due to eruptive rocks, which have been identified as belonging to the eruptive system of the Andes, suggesting a geologically recent connection between South America and the Antarctic lands. Volcanic activity is not yet extinct in the region.

As regards Kaiser Wilhelm Land, the Gaussberg is a volcanic cone mainly composed of leucite-basalt, but its slopes are strewn with detritus presumably transported from the south and these include gneiss, mica-schist and quartzite, apparently Archæan.

Much more is known as to the geology of Victoria Land, and the results are well summarized by Professor David and Mr Priestley of Sir Ernest Shackleton's expedition, whom we follow. From Cape North (78° S.) to 86° S. a grand mountain range runs south curving to south-eastward, where it vanishes into the unknown; it is built up of gneiss and granite, and of horizontal beds of sandstone and limestone capped with eruptive rock, the peaks rising to heights of 8000, 10,000 and even 15,000 feet, the total length of the range so far as known being at least 1100 miles. This range rises abruptly from the sea, or from the ice of the Great Barrier, and forms a slightly higher edge to a vast snow plateau which has been traversed for several hundred miles in various directions, and may for aught we know extend farther for a thousand miles or more. The accumulated snows of this plateau discharge by the hugest glaciers in the world down the valleys between the mountains. About 78° S. a group of volcanic islands, of which Ross Island, with the active Mt Erebous is the largest, rise from the sea in front of the range, and at the northern extremity the volcanic peaks of the Balleny Islands match them in height. The composition of the volcanic rocks is similar to that of the frola in the rocks of the south-west part of Niue Island. The oldest rocks of Victoria Land are apparently banded gneiss and gneissite granite, which may be taken as Archæan. Older Palæozoic rocks are represented by greenish grey slates from the sides of the Beardmore glacier and by radiolarian cherts; but the most widespread of the sedimentary rocks occurring in vast beds in the mountain faces is that named by Ferrar the Beacon sandstones, which in the far south Shackleton found to be banded with seams of shale and coal amongst which a fossil occurred which has been identified as coniferous wood and suggests that the place of the formation is Lower Carboniferous or perhaps Upper Devonian. No Mesozoic strata have been discovered, but deposits of peat derived from fungi and moss are now being accumulated in the fresh-water lakes of Ross Island, and raised beaches show a recent change of level. The coast-line appears to be of the Atlantic, not the Pacific type, and may owe its position and trend to a great fault, or series of faults, in the line of which the range of volcanoes, Mt Melbourne, Mt Erebous, and Mt Discovery stand. Boulders of gneiss, quartzite and sandstone have been dredged at so many points between the Balleny Islands and the Weddell Sea that there can be no doubt of the existence of similar continental land along the whole of that side, at least within the Antarctic Circle.
Polar Regions

Antarctic Ice-Conditions.—It is difficult to decide whether the ice of the polar regions should be dealt with as a geological formation or a meteorological phenomenon; but in the Antarctic the ice is so characteristic a feature that it may well be considered by itself. So far as can be judged, the total annual precipitation in the Antarctic region is very slight, probably not more than the equivalent of 10 in. of rain, and perhaps less. It was formerly supposed that the immense accumulation of snow near the South Pole produced an ice-cap several miles in thickness which, creeping outward all round, terminated in the sea in vast ice-cliffs, such as those of Ross's Great Barrier, whence the huge flat-topped ice-islands broke off and floated away. Evidence, both in the Graham Land and in the Victoria Land areas, points to a former much greater extent of the ice-cap. Thus Shackleton found that the summit of Mt Hope, in 85° 30' S., which stands 2000 feet above the ice of the surrounding glaciers, was strewed with erratics which must have been transported by ice from the higher mountains to the south and west. In McMurdo Sound, as in Graham Land, evidence was found that the surface of the ice-sheet was once at least a thousand feet above its present level. These facts appear to indicate a period of greater snowfall in the geologically recent past—i.e. a period of more genial climate allowing the air to carry more water vapour to the southern mountains. Whatever may have been the case in the past the Antarctic glaciers are now greatly shrunken and many of them no longer reach the sea. Others project into the sea a tongue of hard ice, which in the case of the Drygalski glacier tongue is 50 m. long, and afford probably for a considerable distance. Some of these glacier tongues of smaller size appear now to be cut off at their shoreward end from the parent glacier. At one time the Victoria Land glacier tongues may have been confluent, forming a great ice barrier along the coast similar to the small ice-barriers which clothe the lower slopes of some of the islands in Gerlache Strait. The Great Ice Barrier is in many ways different from these. Captain Scott showed that it was afloat for at least 400 m. of its extent from west to east. Sir Ernest Shackleton followed it for 400 m. from north to south, finding its surface in part thrown into long gentle undulations, but with no evidence of the surface being otherwise than level on the average. The all-but-forgotten experiments and cogitations of Biscoe convinced that shrewd observer that all Antarctic icebergs were sea-ice thickened with snow "accumulated with time." The recent expeditions seem to confirm this view to a great extent in the case of the Barrier, which, so far as the scientific men on the "Nimrod" could see, was formed everywhere of compressed nevé, not of true glacier ice. Instances have been seen of tabular bergs floating with half their bulk above water, showing that they are of very much less density than solid ice. The thrust of the glaciers which descend from the western mountains upon the Barrier throws it into sharp crevassed folds near the point of contact, the disturbance extending 20 m. from the tip of the Beardmore glacier, and the seaward creep of the whole surface of the Barrier is possibly due to this impulse; the rate of movement at the eastern side of the Barrier was found to be at the rate of 500 yds. per annum for the seven years between Scott's and Shackleton's expeditions.

Pack ice composed of broken-up sea-ice and fragments of icebergs appears to form a floating breakwater round the Antarctic area. It is penetrated by powerful steamers with ease or with difficulty according to the action of the wind which loosens the pack when it drives it towards the open sea, and closes it up when it drives it against a coast or a barrier of fast ice. At every point but one around the circumpolar area the pack, be it light or dense, appears to extend upward to the southern permanent ice or land, though, as in the Weddell Sea, the pack seems at times to be driven bodily away. The exceptional region is the opening of the Ross Sea east of Cape Adare, where a comparatively narrow band of pack ice has always been penetrated by the resolute advance even of sailing ships and led to an extensive open sea to the south. No doubt the set of the ocean currents accounts for this, but how they act is still obscure. The great flat-topped ice-islands which in some years drift out from the Antarctic area in great numbers are usually met with in all parts of the Southern Ocean south of 60° S., and worn-down icebergs have been sighted in the Atlantic even as far north as 20° 30' S. The greater frequency of icebergs in the Southern Ocean in some years is attributed to earthquakes in the Antarctic breaking off masses of the floating edge of the Barrier.

Antarctic Climate.—Although a vast mass of observations has recently been accumulated, it is not yet possible to treat of the climate of the South Polar region in the same broad way as in the case of the North Polar region. The following table shows the mean temperatures of each month and of the year at all the stations at which the Antarctic winter has been passed. The result is to show that while the winter is on the whole less severe at high latitudes than at equal latitudes in the north, the summer is very much colder, and has little relation to latitude. Even in the South Orkneys, in latitude 60°, in the three warmest months the air scarcely rises above the freezing point as an average, while in Shetland (60° N.) the temperature of the three summer months averages 54° F. But on the other hand, the warmest month of the year even in 77° S. has had a mean temperature as high as 30°. A study of the figures quoted in the accompanying table shows that until longer records

become available it is impossible to speak definitely as to the normal distribution of monthly temperature throughout the year, for even at the same station in consecutive years the months vary greatly. Thus at Snow Hill (65° S.) the mean temperature of August 1903 was 13° higher than that of August 1902, though June had been 7° colder; and at the "Discovery's" winter quarters July 1903 was 13° colder than July 1902 though June was 2° warmer, August having exactly the same mean temperature in each year. The mean temperature of the year is evidently higher in the position of the "Belgica's" drift than in Victoria Land at the same latitude; but it is noticeable that on the west side of Graham Land, where Charcot wintered, the average mean temperature for the two winters (lowering the average of his two winterings) 13° higher than on the east side, where Nordenstjeld wintered in nearly the same latitude. The observations, however, were not synchronous; and it may not be right to compare them. We may perhaps say that along the whole of the known Antarctic coast the temperature in the two midsummer months is within a degree or two of 32° F., and varies little from place to place or from year to year; but in the winter months the temperature is lower as the latitude increases and is subject to great variations from place to place and from year to year. It seems quite possible that at no place in the Antarctic the mean temperature remains constant, and the temperatures fall so low as in the Arctic poles of cold, but data regarding winter temperatures in the interior are lacking. All the complete yearly series of temperature show that the winter six months from April to September have a low and nearly equal temperature, there being a very abrupt fall in February and March, and an equally abrupt rise in October and November. The warmest day experienced at the "Discovery's" winter-quarters had a mean temperature of 34°; and the coldest -45°, the extreme range of daily temperature being thus 80°.

The absolutely lowest temperature recorded in the Antarctic region was -66° F. on a journey southward from the "Discovery's" winter-quarters by Lieut. Barncroft on the 15th of September 1903; the lowest temperature at the winter-quarters was -58° on the 28th of September 1903. Sir Ernest Shackleton's expedition the lowest temperature was -57°; but no other expedition met temperatures lower than -45° on the "Belgica," -43° 1' at Cape Adare, and -41° 4' on the "Gauss." Sudden rises of temperature during storms are common in the Antarctic region, from whichever quarter the wind blows.

During the ascent of M't Erebus the temperature was found to fall as the height increased from 0° at sea-level to -24° at 5000 ft.; it remained stationary at 8600 ft., fell to -18° at 14,500 ft. and rose to 4° at 17,000 ft. above the snow-line. Temperature at the summit. It might appear as if the "isothermal layer" of the upper atmosphere had been reached at a remarkably low elevation; but the temperature variations may also be explained by differences in the temperature of the strong air currents which were passed through.

Pressure and Winds.—The normal fall of pressure southwards, which gives rise to the strong westerly winds of the roaring forties, appears to be arrested about 65° S., and to be succeeded by a rise of pressure farther south. This view is supported by the frequency of south-easterly winds in the neighborhood of the Antarctic Circle reported by all explorers, and the hyphothesis of a south polar anticyclone or area of high pressure over the Antarctic continent has gained currency in advance of any observations to establish it. The complete data of Sir Ernest Shackleton's expedition are not available at the time of writing, but the yearly mean pressure as recorded at the "Discovery's" winter-quarters was 29.35 in. for 1902, and 29.23 in. for 1903. At Cape Adare it was 29.13 in. for 1899, in the "Belgica" 29.31 in. for 1898, and in the "Gauss" 29.13 in. for 1902. These figures, so far as they are comparable, show distinctly higher pressures in the higher latitudes, and the wind observations bear out the inference of a south-polar high pressure area, as at the "Discovery's" winter-quarters 89% of the winds had an easterly component, and only 3% a westerly component. It is bewildering, however, to find that on the ledge journeys there was an equally marked preponderance of wind with a westerly component, and in discussing the result in the published records of the expedition Mr R. H. Curtis, of the Meteorological Office, felt compelled to ask whether the correction for variation of the compass (in that region about 145°) was possibly omitted in the case of the ledge journeys. The "Gauss" observations and those at Cape Adare bore out the frequency of easterly winds, and on the "Scotia" it was observed that practically all of the easterly winds met with were to the south of the Antarctic Circle. The "Belgica" found rather more westerly than easterly winds in her drift; easterly winds predominating in summer, westerly winds in winter. At Cape Royds Shackleton found easterly winds to predominate, the most frequent direction being south-east; but on the great southern journey, south-south-east winds prevailed, occasionally swinging round to south-south-west, and even at the farthest south (88° S.) the winds into which the snow was blown, 10,000 ft. above the sea, showed that south-southwesterly winds predominated. On the journey to the Magnetic Pole Professor David found that along the coast the prevailing winds were south-west, with occasional blizzards from the south-east, but he noticed that the westerly winds were of the most constant kind, and in many cases there was a marked north-westerly wind continuing to blow fresh until about 10 a.m. Thus the balance of probability inclines towards the hypothesis of a south-polar high-pressure area. An upper current of air blowing from a north-westerly direction was usually indicated by the clouds and smoke on M't Erebus, and on the occasion of a great eruption, when the steam column reached more than 20,000 ft. above the sea it entered a still higher stratum of wind blowing from the south-east.

The intensity of the blizzards is worthy of remark, for the velocity of the wind often reached 40 or even 60 m. an hour, and they were usually accompanied by a rapid rise of temperature. Observations of sunshine made at the "Discovery's" winter-quarters yielded many records of continuous sunshine extending throughout 24 consecutive hours, and in the summer months about 50% of the possible sunshine was often recorded, the maximum being 490 hours, or 66% of the total possible for December 1903. Thus, although the sun was above the horizon only for 24-65 days, it shone sufficiently to yield more than 1725 hours of bright sunshine for the year, an amount exceeded in few parts of England, where the sun may shine on 365 days. The intensity of solar radiation in the clear weather of the Antarctic makes it feel exceedingly hot even when the air temperature is far below the freezing point. There is a difference of 130 ft. between the clear skies of 78° S. and the extremely frequent fogs which shroud the coast near the Antarctic Circle and render navigation and surveying exceedingly difficult. Heavy snow-storms are frequent on the coast, but inland during the snow-blizzards it is impossible to say whether the whirling snow-dust is falling from the air or being swept from the ground. Professor David is inclined to believe that the surface of the snow-plains is being lowered more by the action of the wind sweeping the snow out to sea than it is raised by precipitation, the total amount of which appears to be very small.

Plants and Fauna.—Recent expeditions have discovered that, despite the low temperature of the summer, in which no month has a mean temperature appreciably above the freezing point, there are on the exposed Antarctic land patches of ground with a sparse growth of cryptogamic vegetation consisting of mosses, lichens, fungi and fresh-water algae. The richest vegetation discovered on the "Nimrod" expedition consisted of sheets of a lichen or fungoid growth, covering the bottom of the freshwater lakes near Cape Royds, and visible through the clear ice throughout the many months when the water is frozen. No flowering plants occur within the Antarctic Circle or in the immediately adjacent lands.

The marine fauna is very rich and abundant. All the expeditions obtained many new species, and the resemblance which occurs between many of the forms and those which inhabit...
the Arctic seas has given rise to the hypothesis that certain species have been able to pass from one frigid zone to the other. It is argued on the other hand that all the forms which resemble each other in the two polar areas are cosmopolitan, and occur also in the intermediate seas; but the so-called "problem of bipolarity" is still unsettled. Bird life on sea and land is fairly abundant, the most common forms being the skua gull, snow petrels, and the various species of penguins. The penguins are specially adapted for an aquatic life, and depend for their food entirely on marine animals. The largest species, the emperor penguin, inhabits the most southerly coast known on the edge of the Great Barrier, and there it breeds at mid-winter, very likely due to the richness of the food found and the absence of this apparently impossible feat practicable. The social organization and habits of the various species of penguins have been carefully studied, and show that these birds have arrived at a stage of what might almost be called civilization worthy of the most intelligent beings native to their continent. The only mammalian life in the Antarctic is marine, in the form of various species of whales, but not the "right whale," and a few species of seals which live through the winter by keeping open blow-holes in the ice. Ihere is no trace of any land animal except a few species of minute wingless insects of a degenerate type; and the birds which abound are such forms as the cor- tardigrada, or "water bears" and rotifers showing a remarkable power of resistance to low temperature, being thawed out alive after being frozen solid for months and perhaps for years.

POLDER, the Dutch name for a piece of low-lying, marshy land reclaimed from the sea or other water by drainage and diking (see HOLLAND).

POLE (family). The family of the Poles, earls and dukes of Suffolk, which, but for Richard III.'s defeat at Bosworth, might have given the next king to England, had its origin in a house of merchants at Kingston-upon-Hull. It has been said that these Poles were the first English peers whose fortunes had been founded upon riches gained in trade; but the Berkeleys, descendants of Robert Fitz Harding, the rich burghebers of Gloucester, must perhaps be reckoned before them. Their pedigree begins with one William atte Pole (d. c. 1320), a merchant of Ravens- rode who settled in Hull, where his widow became the wife of John Rotenhering, also a merchant. His sons, Sir Richard and Sir William atte Pole, were both famous for their wealth at a time when the Crown had great need of rich men's aid. Sir Richard (d. 1345), the king's butler in 1327, removed to London, and is styled a London citizen in his will. The male line of this, the elder branch of the Poles, failed with a grandson, John Pole, who by his marriage with Joan, daughter of John, Lord Cobham, was father of Joan, Lady of Cobham, the Kentish peeress whose lands brought her five knightly husbands, the fourth of them Sir John Oldcastle the Lollard.

Sir William atte Pole (d. 1366), the second son of William, joined his brother in advancing large sums to the government while keeping safely apart from politics. The first mayor of Hull, he sat for Hull in five parliaments, and was advanced to be knight banneret and a baron of the exchequer. He was counted "second to no merchant in England," but after his time his descendants left the counting-house, his four sons all serving in the French wars. The eldest son, Michael Pole, who had fought under the Black Prince and John of Gaunt, was summoned as a baron in 1366, before the father's death, and, as a stout supporter of the Crown, was appointed in 1381 governor of the person of the young king Richard II., whose marriage with the Lady Anne of Bohemia he had arranged on a visit to her brother the king of the Romans. In 1383 he became chancellor of England and thereafter, as the loyal servant and nearest counsellor of the king, he had to face the jealousy of the great lords and the hatred of the Commons. His wealth added to the envy of his enemies, for, to his inherited Yorkshire and Lincolnshire lands, his marriage with Catherine, daughter and heir of Sir John of Wingfield, added a great Suffolk estate, where, fortifying the manor-house of the Wingfields, he made his chief seat. In 1385 he was created earl of Suffolk, and from the Crown giving him the castle and honour of Eye with other East Anglian lands formerly held by the Suffolk earls. In 1386 the opposition, led by Gloucester, the king's uncle, pulled him down. He was dismissed from his chancellorship, and impeached by the Commons on charges which, insufficient upon the face of them, secured his conviction. Richard was forced to send his minister into ward at Windsor until the parliament was dissolved, when Suffolk once more appeared as the leader of the king's party. But the opposition was insistent, and Suffolk, after Richard had been compelled to give his word that those who had advised him ill should answer for it to the next parliament, fled over sea to Calais. One of the innumerable letters from his supporters that bade against the Poles tells joyfully of this flight of the detained "Jake." Sentence of death by the gallows was passed in his absence. The over-zealous governor of Calais who found him at his gates, clad as a poor Fleming, his chin shaved, packed him back to England, whence he escaped again, doubtless with the king's aid, reaching his native town of Hull, where he saw for the last time his "goodly house of brick." Old friends found him a ship that landed him in the Low Countries, and he died an exile in Paris in 1389.

The exile's son Michael, who had married Catherine, daughter of the earl of Stafford, was restored to the earldom in 1397, and, although his father's attainder was revived by the act of the first parliament of Henry IV., the earldom was restored once again in 1399, together with the castle and honour of Eye. His life was that of a soldier, and he was with the host before Har- fleur in 1415, when he died of a violent dysentery. Michael, the eldest son and heir, marched from his father's deathbed to Agincourt, where he fell, Drayton's ballad recalling how he plied his axe on the great day. By his wife, a daughter of the first duke of Norfolk, he had three daughters, but no one of them marrying, his lands passed with the earldom to his brother William.

This William (1366-1430), the fourth earl of his name, had sailed with his father and elder brother to Harlefre, but had
been sent home sick after the siege. He returned with the "viage" of 1417, leading thirty men-at-arms and ninety archers. Henry V. made him admiral of Normandy, and until the crowning of Henry VI. in Paris in 1431 he served in France without, by his own account, coming home or seeing England. He held the chief command before Orleans after Salisbury had fallen to a cannon-shot from the city, but was forced to surrender to Joan of Arc at Jargeau, where his brother Alexander was killed, another brother, John, being taken prisoner with the earl. A fourth brother, Thomas, a clerk, became hostage to Dunois until the vast ransom of the earl was paid down. After that Suffolk turned to English politics. Like his grandfather, he found a king's uncle, another Gloucester, the chief of his enemies. Defeating Gloucester's project of an Armagnac match, Suffolk arranged for the young king's marriage with Margaret of Anjou, and brought home the bride to Portsmouth in 1445. In the year before he had been created marquess of Suffolk, being the fourth Englishman to take the style of marquess. His party and the queen's were on the point of overthrowing their opponent, Gloucester, when the "good duke" died suddenly in the hands of those who had arrested him. This death, followed by that of Cardinal Beaufort, left the field to Suffolk. Under him Suffolk ruled England, as the splendid descendent of the great family of Pembridge, Duke Humphrey's death. His honours were capped in 1448 with a dukedom of Suffolk, himself then admiral of England, governor of Calais, constable of Dover, and warden of the Cinque Ports. But it seemed that long service in the foreign wars had not purged the offence of the name of Pole. All the old enmity which had driven his grandfather into exile was gathering against Suffolk. His peace policy had cost the cession of Maine and Anjou, while the blunders of his ally, Somerset, as lieutenant in France, lost Normandy to England. Early in 1450 the Commons, in spite of Suffolk's appeal to his years of loyal service, accused him of treason and he was sent to the Tower. A long indictment was reinforced by new accusations, and the king could do no more for his minister than set him free under a sentence of five years' banishment. He sailed from Ipswich on the May Day of 1450, but before he could enter the port of Calais he was cut off by a royal ship, the "Nicholas," whose master had him put overboard into the cockpit, where his head was hacked off by an Irish knave's rusty sword. His body, cast headless upon Dover beach, was carried by the king's orders to the Poles' vault in Wingfield church, where his effigy may still be seen. Who sent out the "Nicholas," and by whose orders Suffolk died, are questions which remain unanswered. He was the third husband of Suffolk, although he was never the wife of Thomas, Earl of Salisbury, slain before Orleans. She was the daughter and heiress of Thomas Chaucer, of Ewelme, and, although direct evidence is wanting, the granddaughter, without doubt, of Geoffrey Chaucer, the poet. She lies at Ewelme, under a magnificent tomb.

John Pole (1442-1491), only son of the murdered duke, should have succeeded to the dukedom, his father having died unattainted. But the honours were apparently regarded as forfeited, and the dukedom was formally restored to the boy in 1455, the earldom of Pembroke being allowed to lapse. Although three generations of warrior lords lay between him and the Hall warehouses, the origin of his house was still fresh in men's memories. John Paston, writing in 1465, could tell every name in the duke's pedigree back to "William Pool of Hull," who had been "first a merchant and after a knight," and "what the father of the said William was" John Paston knew "right well." The duke's father was an upstairs for the crowd, whose ballads pelted him with the name of "Jac Napes," suggested by his familiar badge of the ape's clog and chain. Nevertheless a wife of royal blood was found for the young duke, King Edward IV.'s own sister Elizabeth. The marriage confirmed him a partisan of the White Rose. The son of Margaret's faithful minister rode against her man at the second battle of St Albans. Before he was of age he was steward of England at his brother-in-law's crowning, and at Queen Elizabeth's crowning he bore her sceptre. Having held many offices under Edward IV. he was ready to bear a sceptre at Richard's coronation, and, after Bosworth, to swear fealty to the Tudor dynasty and to bear another sceptre for another Queen Elizabeth. He died in 1491, having safely kept his lands, his dukedom, and his head through perilous years.

But each advance in rank had brought danger and misfortune to the Poles. Before the death of the second duke they had begun to pay the price of their matching with the royal house. In the next generation their name was blotted out. John Pole, eldest son of Duke John and the Lady Elizabeth, had been created Earl of Lincoln by his uncle, Edward IV. Before he followed Richard to Bosworth, the young man had been chosen as heir to the throne, Clarence's son Warwick being put aside. He survived King Richard and Henry VII. spared him. But he egged on Simmell's plot, joined the rebels in Ireland, and was killed at Stoke in 1487, leaving no issue by his wife, the daughter of the earl of Arundel. Edmund, his younger brother, (c. 1472-1513) should have succeeded in 1491 as duke of Suffolk, but on coming of age he agreed to satisfy himself with the title of Duke of Norfolk. The king gradually restored some portion of the estates forfeited by his father in 1490.

In 1499 he suddenly left the kingdom, but was persuaded to return. But the death of the imprisoned earl of Warwick may have suggested to him that Henry's court was a dangerous place for those of the blood of York, and in 1501 he found his way to the emperor Maximilian in Tirol with a scheme for the invasion of England. Although the kaiser at first promised him men for the adventure, nothing came of his promises. Maximilian, persuaded by a gift of English money, hound himself not to succour English rebels. Suffolk, who had reassumed the ducal style, was attainted in 1504, and in the same year was seized by the duke of Guelders. From the duke's hands the prisoner was taken by Philip, king of Castile, who surrendered him to England on a promise that his life should be spared. But in 1513, when Richard, his brother, was in arms in the French service, Edmund Pole was taken from his prison in the Tower to the block.

Richard Pole, who in 1501 escaped from England with Edmund, had been received by the king of Hungary, and afterwards by Louis of France, who assigned him a pension. Commanding German Lanzenknechts in the French service, he was the friend and companion in arms of the chevalier Bayard. At the death of his brother Edmund, he took the title of the earl of Suffolk, the name of the great chief of the house of Suffolk by Philip, king of Castile, who surrendered him to England on a promise that his life should be spared. De unitate ecclesiastica, the whole family fell under the displeasure of the king, who resolved to make an end of them. The Lord Montague was the first victim, beheaded in 1539 on a charge of treasonable conversations, evidence of which hath been brought against an unhappy brother, Sir George Pole. In 1541 the aged countess, attainted with her son Montague, met her death at the barbarous hands of an unskilful head-smith. Sir George Pole, seeing that his house was doomed, fled the country, and joined the cardinal in exile. He returned with him to Mary’s accession, both dying in 1558. His sons Arthur and Edmund, taken in 1562 as plotters against Queen Elizabeth, were committed to the Tower of London, where they died after eight years of imprisonment.

POLE, REGINALD (1500-1558), English cardinal and archbishop of Canterbury, born at Stourton Castle, Staffordshire, was the third son of Sir Richard Pole, Knight of the Garter, and Margaret, Countess of Salisbury, a daughter of George, Duke of Clarence, and therefore niece of Edward IV. He was intended for the church from his youth; and when seven years old was sent for five years to the grammar school which Cole had founded near his castle at Sheen. Here he had Linacre and William Latimer as teachers. In his thirteenth year he went to Magdalen College, Oxford, and two years after took his degree in arts. In 1517 Henry VIII. appointed his young kinsman to a prebend in Salisbury, and soon afterwards to the deaneries of Wimborne and Exeter. He was a friend of Sir Thomas More, who says that Pole was as learned as he was noble and as virtuous as he was learned. In 1519, at the king’s expense, he went to Padua, the Athens of Europe, according to Erasmus; and there, where Cole and Cuthbert Tunstall had also been educated, the “nobleman of England” as he was called, came into contact with the choicest minds of the later Italian Renaissance, and formed the friendships that influenced his life.

In 1525 he went to Rome for the Jubilee, and two years after returned to England and was initiated by Thomas Cromwell into the mysteries of statesmanship, that master telling him that the main point consisted in discovering and following the will of princes, who are not bound by the ordinary code of honour. When the divorce question arose, Pole, like many other excellent men, seems at first to have been in its favour. He probably took the same view that Wolsey had, viz., that the dispensation of Julius II. was insufficient, as of two existing diriment impediments only one had been dispensed. When however the king turned the theological argument which ended in disaster, Pole could not accept it; and, after the failure of Camppeggio’s mission, when the king asked him for his opinion, he excused himself on the score of inexperience, but went by Henry’s order to Paris (1530) to obtain the judgment of the Sorbonne, making the condition that another should be joined with him to do the necessary business. At this time, he says, the more he saw into the case the less he knew how to act as he was desired. On his return to England he spoke strongly against the project to the king, who seems to have dealt gently with him in the hope of using him for his own ends. He offered him the see of Bath or Winchester, and the curia. but he refused both for months for his own peace. There was a stormy interview at York Place; but Pole succeeded in mollifying the king’s rage so far that Henry told him to put into writing his reasons against the divorce. This was done, and, recognizing the difficulties of the situation, the king gave him leave to travel abroad, and allowed him still to retain his revenues as dean of Exeter. In 1535, which saw by the deaths of Bishop Fisher and Sir Thomas More a change in Henry’s policy, Pole received orders to send

a formal opinion on the royal supremacy, and the king promised to find him suitable employment in England, even if the opinion were an adverse one. The parting of the ways had come. Pole’s republic, which took a year to mature, and was afterwards published with additions under the title Pro unitate ecclesiastica, was sent to England (May 25, 1539) and was meant for the king’s eye alone. It contained a vigorous and severe attack upon the royal policy, and did not shrink from warning Henry with temporal punishment at the hands of the emperor and the king of France if he did not repent of his cruelties and return to the Church. He was again summoned to return to England to explain himself, but declined until he could do so with honour and safety; but he was on the point of going at all risks, when he heard from his mother and brother that the whole family would suffer if he remained obstinate. Paul III. who had prepared a bull of excommunication and deposition against Henry, summoned Pole to Rome in October, and two months after created him cardinal. In January 1537 he received a sharp letter of rebuke from the king’s council, together with the suggestion that the differences might be discussed with royal deputies either in France or Flanders, provided that Pole would attend without being commissioned by any one. He replied that he was willing and had the pope’s leave to meet any deputies anywhere. Paul III. in the early spring of that year named him legate a latere to Charles V. and Francis I., for the purpose of securing their alliance in enforcing the bull by helping a projected rising in England against Henry’s tyranny. The mission failed, as the mutual jealousy of the sovereigns would not allow either to begin operations. Moreover, the fear of Henry was sufficient to make the French king refuse to allow one who was attainted by act of parliament to remain in the kingdom; so Pole passed over to Flanders, to wait for the possible arrival of any royal deputies. The proposed conference never took place, and in August 1537 the cardinal returned to Rome. There he was appointed to the famous commission which Paul III. established for considering the reforms necessary for the church and Roman curia. The report Consilium delectorum cardinalium is, in its plain-spoken directness, one of the most noteworthy documents of the history of the period. Towards the end of 1539, after Henry had destroyed the abrine of St Thomas Becket, another attempt was made to launch the bull of deposition, and Pole again was sent to urge Charles V. to assist. Once more his efforts were in vain, and he retired to his friend Sadoleto at Carpentras. As Pole had escaped Henry’s power the royal vengeance now fell on his mother, who was executed as a traitor on the 27th of May 1541. When the news came to the cardinal he said to his secretary Beccatelli that he had received good tidings: “Hitherto I have thought myself indebted to the divine goodness for having received my birth from one of the most noble and virtuous women in England; but henceforth my obligation will be much greater, as I understand I am now the son of a martyr. We have one patron more added to those we already have in heaven”; and returning to his oratory Pole found peace in his sorrow.

On the 21st of August 1544 the cardinal was appointed legate at Viterbo, and for a few years passed a happy and congenial life amid the friends that gathered round him. Here he came into close relations with Vittoria Colonna, Contarini, Sadoleto, Bembo, Morone, Marco Antonio Flaminio, and other scholars and leaders of thought; and many of the questions raised by the Reformation in Germany were eagerly discussed in the circle of Viterbo. The burning question of the day, however, was the value of the marriage by Henry of Anne Boleyn. The “dole libellinae,” the famous Trattato utilissimo del beneficio di Gesu Christo cresctfoe verso i christian, which was the composition of a Sicilian Benedictine and had been touched up by the great Latinist Flaminio, just appeared at Mantua in 1542 under the auspices of Morone, and had a wide circulation (over 40,000 copies of the second edition, Venice 1543, were sold). Containing extracts from the Hundred and Ten Divine Considerations of Juan Valdes (q.v.),
it was soon regarded with the utmost horror by many. But at Viterbo it was in favour, and the orthodox interpretation was regarded rather than the other which might be taken in the Lutheran sense. Pole's own attitude to the question of justification by faith is given by Vittoria Colonna, to whom he said that she ought to set herself to believe as though she must be saved by faith alone and to act as though she must be saved by works alone. In the excited temper of the times any defender of justification by faith was looked upon by the old school as heretical; and Pole, with the circle at Viterbo, was denounced to the Inquisition, with all sorts of crimes imputed to him. Though the process went on from the pontificate of Paul III. to that of Paul IV., nothing was done against the cardinal until the time of the latter pope, who was his personal enemy. It is by no means certain that Pole even knelt at the general pardons; and immediate subsequent events show that no censure was given to the charges.

While at Viterbo his rule was firm but mild; and no charge of persecuting heretics is made against him. He regained many, such as his friend Flaminio, by patience and kindliness, to a reconsideration of their errors. During this time also he was still engaged in furthering a proposed armed expedition to Scotland to aid the papal party, and in 1545 he was again asking help from Charles V. But the Council of Trent (1545), first summoned in 1546, was at last on the point of meeting, and this required all his attention. In 1542 he had been appointed one of the presiding legates and had written in preparation his work De Concilio; and now in 1545, after a brief visit to Rome, he went secretly, on account of fear of assassination by Henry's agents, to Trent, where he arrived on the 4th of May 1545. At the council he took a high spiritual line, and his learning and devout life made him a great leader in that assembly. He advocated that dogmatic decrees should go together with those on reform as affording the only stable foundation. His views on the subject of original sin, akin as it is to that of justification, were accepted and embodied in the decree. He was present when the latter subject was introduced, and he entreated the fathers to study the subject well before committing themselves to a decision. On the 28th of June 1546 he left Trent on account of ill-health and went to Padua. While he was there frequent communications passed between him and the council and the draft of the decree on justification was sent to him. His suggestions and amendments were accepted, and the decree embodies the doctrines that Pole had always held of justification by a living faith which showed itself in good works. This effectually disproves the story that he left the Council of Trent so as to avoid taking part in an adverse decree.

On the death of Henry (Jan. 28, 1547), Pole by name, was left at the general pardon; and in the subsequent rising in the West the insurgents demanded that he should be sent for and made the first on the record in the council. He wrote several times to England to prepare a conference, but only received a rude reply from Somerset, who sent him a copy of the Book of Common Prayer. At the close of 1549 Pole received two-thirds of the votes, but by a delay, caused by his sense of responsibility, he lost the election and Julius III. succeeded. He then retired to Magazzano on the Lake of Garda and occupied himself by editing his book Pro uniate ecclesiae, with an intended dedication to Edward VI.

The accession of Mary opens the third period of his life. On the 5th of August 1553 he was appointed legate to the new queen and began his negotiations. But many difficulties were put in the way of return. He was still under attainder; and the temper of England was not yet ripe for the presence of a cardinal.

The project of the queen's marriage was also an obstacle. A marriage between her and Pole, who was then only a deacon, was proposed by some, but this did not at all meet the views of the emperor, who therefore hindered him the more from setting out for England. The marriage with Philip, of which Pole did not approve, having taken place (July 25, 1554), and Rome yielding on the practical difficulties of the hay holders of Church lands, a parliament favourable to the proposed union now assembled, and Pole was allowed to return to England as cardinal. On his landing he was informed that the attainer had been reversed; and he received the royal patent authorizing his performance of the legatine duties within the realm. Arriving at Whitehall, where he was received with joy by Mary and Philip on the 30th of November, he proceeded to parliament and there the concessions of the two previous popes' names the demands respecting ecclesiastical property. He entered wisely on his work of reformation, for which he was well prepared. One of the most important matters he had to deal with was to rectify the canonical position of those who had been ordained or consecrated since the breach with Rome. Acting according to the instructions he had received from Rome, where the matter had been fully gone into, he made an investigation, and divided the clergy ordained after that period into two classes; one consisting of those ordained in schism, indeed, but according to the old Catholic rite, and the other of those who were ordained by the new rite drawn up by the council and enforced by act of parliament 1st of April 1530. The first class, after submission, were absolved from their irregularity, and, receiving penance, were reinstated; the second class were simply regarded as laymen and dismissed without penance or absolution. At his first convocation he exhorted the bishops to use gentleness rather than rigour in their dealings with heretics; and Pole, in himself, was true to his principle. He was not responsible for the cruel persecution by which the reign was disfigured. On the 4th of November 1553 Pole opened, in the chapel royal at Westminster, a legatine synod, consisting of the mitred bishops of the two provinces, and the purpose of laying the foundations of wise and solid reforms. In the Reformatio Anglie which he brought out in 1556, based on his Legatine Constitutions of 1555, he ordered that every cathedral church should have its seminary, and the very words he uses on this subject seem to have been copied by the Council of Trent in the twenty-third session (1563). He also ordered that the Catechism of Caranza, who, like him, was to suffer from the Inquisition for this very book, should be translated into English for the use of the laity. On Cranmer's deprivation, Pole became archbishop of Canterbury; and, having been ordained priest two days before, he was consecrated on the 22nd of March 1556, the day after Cranmer suffered at Oxford.

Soon afterwards the clouds began to gather round him. His personal enemy Caraffa had become pope under the name of Paul IV. and was biding his time. When Rome quarrelled with Spain, and France, on behalf of the pope, took up arms, England could no longer observe neutrality. To injure Spain and heedless of England's need, Paul IV. deprived Pole of his power both as legate a latere and legatus natus as archbishop of Canterbury (June 14, 1557); he also reconstituted the process of the Inquisition against the cardinal and summoned him to Rome to answer to the crime and heresies imputed to him. No remonstrances on the part of the queen, or Pole or the English clergy could induce the pope to withdraw his sentence except to declare that the cardinal still held the position of legatus natus inherent in the primatial see. In a dignified but strong letter Pole says: "As you are without example in what you have done against me, I am also without an example how I ought to behave to your Holiness": and he drew up a paper containing an account of the various acts of hostility he had experienced from the pope, but on second thoughts he burnt the document, saying it were not well to discover the shame of his father. Mary, who had been warned by her ambassador to the pope that prison awaited Pole, prevented the brief ordering the cardinal to proceed to Rome from being delivered,

1 See, however, Herzog-Hauck, Realencykleopadie (ed. 3) § "Pole," where it is said that "only his procrastination, and then his death saved him from appearing before the Inquisition." Within the institution of the Inquisition his name continued to be regarded as that of a heretic, and the censures incurred in papal sentences are probably based on the mass of evidence accumulated against him in the Compendium inquisitionum (v. archivio della società di storia patria, Rome, 1880), p. 283, etc.—(Ed.)
POLE, R. DE LA—POLE

and so remained in England. Broken down as much by the blow as by ill-health the cardinal died at Lambeth on the 17th of November 1538, twelve hours after Mary's death and under the unmerited disgrace of the papacy in defence of which he had lost his life. He was buried at Canterbury near the spot where the shrine of St Thomas Becket once stood.

The chief sources for Pole's biography are his life written in Italian by his son Henry Pole (1556) and his letters (Epistolae Reginaldi Poli) edited by Girolamo Quirini and published in 5 volumes (Brescia, 1743-1757), a new edition of which is in press at Rome under the supervision of the Commissions from the Archives. See also the State Papers (foreign and domestic) of Henry VIII, Edward VI, and Mary; the Spanish and Venetian State Papers; vol. ii. A. Thiene's Acta genuina S.S. Ordonnanz (1557); papal processi del sindaco affiutta di Roma dal Paolo III. a Paolo IV. (Società romana di storia patria, Archivio, iii. 261 seq.); T. Phillippi's History of the Life of R. Tns.)

POLE, RICHARD DE LA (d. 1529), pretender to the English crown, was the fifth son of John de la Pole (1442-1491), 2nd duke of Suffolk, and Elizabeth, second daughter of Richard, duke of York and sister of Edward IV. His eldest brother John de la Pole, earl of Lincoln (c. 1464-1487), is said to have been named heir to the throne by his uncle Richard III., who gave him a pension and the reversion of the estates of Lady Margaret Beaufort. On the accession of Henry VII., however, Lincoln took the oath of allegiance but in 1487 he joined the rebellion of Lambert Simnel, and was killed at the battle of Stoke. The second brother Edmund (c. 1472-1513), succeeded his father while still in his minority. His estates suffered under the attaint of his brother, and he was compelled to pay large sums to Henry VII. for the recovery of part of the forfeited lands, and also to exchange his title of duke for that of earl. In 1501 he sought the German King Maximilian in Tirol, and received from him a promise of substantial assistance in case of an attempt on the English crown. In consequence of these treasonable proceedings Henry seized his brother William de la Pole, with four other Yorkist noblemen. Two of them, Sir James Tyrell and Sir John Wyndham, were executed, William de la Pole was imprisoned and Suffolk outlawed. Then in July 1502 Henry concluded a treaty with Maximilian by which the king bound himself not to countenance English rebels. Presently Suffolk fell into the hands of Philip, king of Castile, who imprisoned him at Namur, and in 1506 surrendered him to Henry VII. on condition that his life was spared. He remained a prisoner until 1513, when he was beheaded at the time his brother Richard took up arms with the French king. Richard de la Pole joined Edmund abroad in 1504, and remained at Aix as surety for his elder brother's debts. The creditors threatened to surrender him to Henry VII., but, more fortunately than his brother, he found a safe retreat at Buda under King Ladislas VI. of Hungary. He was excepted from the general pardon proclaimed at the accession of Henry VIII., and when Louis XII. went to war with England in 1512 he recognized Pole's pretensions to the English crown, and gave him a command in the French army. In 1513, after the execution of Edmund, he assumed the title of earl of Suffolk. In 1514 he was given 12,000 German mercenaries ostensibly for the defence of Brittany, but really for an invasion of England. These he led to St Malo, but the conclusion of peace with England prevented their embarkation. Pole was required to leave France, and he established himself at Metz, in Lorraine, and lived there at the Haute Pierre at Casteren. He had numerous interviews with Francis I., and in 1523 he was permitted, in concert with John Stewart, duke of Albany, the Scottish regent, to arrange an invasion of England, which was never carried out. He was with Francis I. at Pavia and was killed on the field on the 24th of February 1525.

POLE, WILLIAM (1814-1900), English engineer, was born at Birmingham on the 22nd of April 1814. He was a man of many accomplishments. Having spent his earlier years in various engineering occupations in England, he went out to India in 1844 as professor of engineering at Elphinstone College, Bombay, where he had to first organize the course of instruction for native students, but his health obliged him to return to England in 1848. For the next ten years he worked in London under James Simpson and J. M. Rendel, and the high reputation he achieved as a scientific engineer gained his appointment in 1859 to the chair of civil engineering in University College, London. He obtained a considerable amount of official work from the government. He served on the committees which considered the application of armours to ships and fortresses (1864), and the comparative advantages of Whitworth and Armstrong guns (1863-1865). He was secretary to the Royal Commission on Railways (1865-1867), the Duke of Richmond's Commission on London Water (1867-1869), also taking part in the subsequent proceedings for establishing a constant supply, the Royal Commission on the Disposal of London Sewage (1882-1884), and the departmental committee on the science museums at South Kensington in 1885. In 1871 he was employed by the War Office to report on the Martini-Henry rifle, and in the same year was appointed consulting engineer in London to the Japanese government, a position through which he exercised considerable influence on the development of the Japanese railway system. He was elected a fellow of the Royal Society in 1861, in recognition of some investigations on colour-blindness. Music was also one of his chief interests. At the age of twenty-two he was appointed organist of St Mark's, North Audley Street, in open competition, the next selected candidate being Dr E. J. Hopkins (1818-1901), who subsequently was for fifty years organist of the Temple Church. He took the degree of Bachelor of Music at Oxford in 1866, proceeding to his doctor's degree in 1867, and in 1879 published his Philosophy of Music. He was largely concerned in the institution of musical degrees by the University of London in 1877, and for many years acted as one of the examiners. His mathematical tastes found congenial occupation in the study of whist, and as an exponent of the scientific principles of that game he was even earlier in the field than "Cavendish." His literary work included treatises on the steam-engine and on iron construction, biographical studies of famous engineers, including Robert Stephenson and I. K. Brunel, Sir William Fairbairn and Sir W. Siemens, several books on musical subjects and on whist, and many papers for reviews and scientific periodicals. He died on the 30th of December 1900. His son, William Pole (1852- ), became known as an actor and writer under the stage-name of William Pole, more especially for his studies in Shakespearean drama and his work in connection with the Elizabethan Stage Society.

POLE (1) (O.Eng. pöel, cf. Ger. Pfahl, Du. paal, from Lat. palus, stake), a tapering cylindrical post or stake of some considerable length, used as a support in scaffolding, for telegraph or telephone wires, hopes, &c., and as a means for taking jumps (see POLE-Vaulting), and also as a single shaft for a vehicle drawn by two or more horses. As a measure of length a "pole," also called "rod" or "perch," is equal to 53 yds. (163 ft.), as a measure of area it is equal to 30 sq. yds. (2) (Lat. polus, adapted from Gr. ἀξος, pivot, axis), one or other of the extremities of the axis of the earth; the "celestial pole" is one of the points in the heavens to which the earth's axis points; in the northern heavens the North Star Polaris is the nearest star Ursae minoris, better known as the Pole-star or Polaris (see Ursa Major). For the regions lying about the north and south poles of the earth see POLAR REGIONS.

In mathematics the word pole has several meanings. In spherical trigonometry the "pole" of a circle on a sphere is the point where the diameter of the sphere perpendicular to the plane of the circle intersects the sphere. In crystallography the term "pole of a face is the intersection of a line perpendicular to the face with
POLECAT—POLE-VAULTING

The Common Polecat.

The polecat ranges over the greater part of Europe, reaching northwards into southern Sweden and in Russia to the region of the White Sea. It does not occur in the extreme south, but is common everywhere throughout central Europe. In the Alps it ranges far above the tree-line during the summer, but retreats in winter to lower ground. It is confined to the northern counties of England and Scotland, where it is becoming very rare, owing to persecutions from game-keepers, and in Ireland it appears to be extinct. In fine weather it lives either in the open air, in holes, fox-ears, rabbit-warrens, under rocks or in wood-stacks; while in winter it seeks the protection of deserted buildings, barns or stables. During the day it sleeps in its hiding place, sallying forth at night to plunder dovecots and hen-houses. It climbs but little, and shows far less activity than the marten. It feeds ordinarily on small mammals, such as rabbits, hamsters, rats and mice, on such birds as it can catch, especially poultry and pigeons, and also on snakes, lizards, frogs, fish and eggs. Its prey is devoured only in its lair; but, even though it can carry away but a single victim, it commonly kills everything that comes in its way, often destroying all the inhabitants of a hen-house in order to gratify its passion for slaughter. The pairing time is towards the end of the winter, and the young, from three to eight in number, are born in April or May, after a period of gestation of about two months. The young, if taken early, may be easily trained, like ferrets, for rabbit-catching. The polecat is very tenacious of life and will bear many severe wounds before succumbing; it is also said to receive with impunity the bite of the adder. Its flesh well has become proverbial. To this it is indebted for its generic name Putorius (derived, as are also the low Lat. putacius, Fr. puilou, and Ital. pusola, from puolo), as well as the designation fomuart (i.e. foul marten) and its other English names, fitchet, fitchew. Attempts to account for the first syllable of the word polecat rest entirely on conjecture.

The Siberian polecat (Putorius caceriunm) is very like the European in size, colour and proportions, but with head and back both nearly or quite white, and skull more heavily built and sharply constricted behind the orbits, at least in fully adult individuals. It inhabitsthe greater part of south-western Siberia, extending from Tibet into the stops of south-eastern Europe.

The black-footed or American polecat (Putorius nigriceps) is a native of the central plateau of the United States, and extends southwards into Texas. It is often called the prairie-dog hunter, as it is nearly always found in the warrens of that animal. The fur is cream-yellow, the legs are brown, and the feet and tail-tip black.

The mottled polecat (Putorius sarmaticus), a species occurring in southern Russia and south-western Asia, and extending from the western Pola to Afghanistan, differs from other polecats by its smaller size and its remarkable colouration, the whole of the upper-parts being marbled with large irregular reddish spots on a white ground, while the under-side, limbs and tail are deep shining black. Its habits appear to be much like those of the common polecat.

(R. L. *)

POLENTA, DA, the name of a castle in Romagna, from which came the noble and ancient Italian family of Da Polenta. The founder of the house is said to have been Guido, surnamed l’Antico or the Elder, who wielded great authority in Ravenna in the 13th century. His grandson Guido Novello upheld the power of the house and was also capitano del popolo at Bologna; he was overthrown in 1322 and died the following year. His chief claim to renown lies in the fact that in 1321 he gave hospitality to the poet Dante, who immortalized the tragic history of Guido’s daughter Francesca, unhappily married to Malatesta, lord of Rimini, in an episode of the Inferno. Guido’s kinsman Ostasio I. was lord of Cervia and Ravenna from 1322 to 1329, and, after being recognized as a vassal of the Holy See, again became independent and went over to the house of Este, whom he served faithfully in their struggles with the Church until his death in 1346. His son Bernardino, who succeeded him as lord of Ravenna in 1346, was deposed in 1347 by his brothers, especially Lamberto II., but was reinstated a few months later and ruled until his death in 1359; he was famous for his profligacy and cruelty. His son Guido III. ruled more mildly and died in 1390. Then followed Ostasio II. (d. 1390), Obizio (d. 1431), Pietro (d. 1404), Aldobrandino (d. 1406), all sons of Guido III. Ostasio III. (or V.), son of Obizio, was at first allied with the Venetians; later he went over to the Milanese, and, although he again joined the Venetians, the latter never forgave his intrigue with their enemies, and in 1441 they deprived him of his dominions. He died in a monastery in 1447.

POLE-VAULTING, the art of springing over an obstacle with the aid of a pole or staff. It is probable that an exercise of the kind was a feature of Greek gymnastics, but with this exception there is no record of its ancient practice as a sport. As a practical means of passing over such natural obstacles as canals and brooks it has been made use of in many parts of the world, for instance in the marshy provinces along the North Sea and the great level of the fens of Cambridgeshire, Huntingdonshire, Lincolnshire and Norfolk. The artificial draining of these marshes brought into existence a network of open drains or canals intersecting each other at right angles. In order to cross these dryshod, and at the same time avoid tedious round-about journeys over the bridges, a stack of jumping poles was...
kept at every house, which were commonly used for vaulting over the canals.

As a sport, pole-vaulting made its appearance in Germany in the first part of the 19th century, when it was added to the gymnastic exercises of the Turnverein by Johann C. F. Guts-Muths and Frederich L. Jahn. In Great Britain it was first commonly practised at the Caledonian games. It is now an event in the athletic championships of nearly all nations. Although strength and good physical condition are essential to efficiency in pole-vaulting, skill is a much more important element. Broad-jumping with the pole, though the original form of the sport, has never found its way into organized athletics, the high jump being the only form recognized. The object is to clear a bar or latch supported upon two uprights without knocking it down. The pole, of hickory or some other tough wood, is from 13 to 15 ft. long and 1½ in. thick in the middle, tapering to ¼ in. at the ends, the lower of which is truncated to prevent sinking into the earth and shred with a single spike to avoid slipping. A hole in which to place the end of the pole is often dug beneath the bar. In holding the pole the height of the cross-bar is first ascertained, and the right hand placed, with an undergrip, about 6 in. above this point, the left hand, with an over-grip, being from 14 to 30 in. below the right. The vaulter then runs towards the bar at full speed, plants the spiked end of the pole in the ground about 18 in. in front of the bar and springs into the air, grasping the pole firmly as he rises. As he nears the bar he throws his legs forward, and, pushing with shoulders and arms, clears it, letting the pole fall backwards. In Great Britain the vaulter is allowed to climb the pole when it is at the perpendicular. Tom Ray, of Uiverston in Lancashire, who was champion of the world in 1887, was able to gain several feet in this manner. In the United States climbing is not allowed. Among the best British vaulters, using the climbing privilege, have been Tom Ray, E. L. Stones, R. Watson and R. D. Dickinson; Dickinson having cleared 11 ft. 9 in. at Kidderminster in 1891. The record pole-vault is 17 ft. 6½ in., made by W. Tray of Yale in 1907.

**POLICE** (Fr. *polic*, government, civil administration, a police force, Gr. *politeia*, constitution, condition of a state, *polis*, city, state), a term used of the enforcement of law and order in a state or community, of the department concerned with that part of the civil administration, and of the body or force which has to carry it into execution. The word was adopted in English in the 18th century and was disdained as a symbol of foreign oppression. The first official use appears, according to the *New English Dictionary*, in the appointment of "Commissioners of Police" for Scotland in 1714. A police system has been devised for the purpose of preventing evils and providing benefits. In its first meaning it protects and defends society from the dissidents, those who decline to be bound by the general standard of conduct accepted by the larger number of the law-abiding, and in this sense it is chiefly concerned with the prevention and pursuit of crime. It has a second and more extensive meaning as applied to the regulation of public order and enforcing good government.

**United Kingdom.**—The establishment of a systematic police force was of slow growth in England, and came into effect long after its creation abroad. A French king, Charles V., is said to have been the first to invent a police, "to increase the happiness and security of his people." It developed into an engine of horrible oppression, and as such was repugnant to the feelings of a free people. Yet as far back as the 13th century a statute, known as that of "Watch and Ward," was passed in martial fashion by Edward I. (1258), aimed at the maintenance of peace in the city of London. Two centuries later (1585) an act was passed for the better government of the city and borough of Westminster, and this act was re-enacted with extended powers in 1737 and soon succeeded by another (1777) with wider and stricter provisions. The state of London at that date, and indeed of the whole country at large, was deplorable. Crime was rampant, highwaymen terrorized the roads, footpads infested the streets, burglaries were of constant occurrence, river thieves on the Thames committed depredations wholesale. The watchmen appointed by parishes were useless, inadequate, inefficient and distrustworthy, acting effective as accessories in aiding and abetting crime. Year after year the shortcomings and defects were emphasized and some better means of protection were constantly advocated. At the commencement of the 19th century it was computed that there was one criminal to every twenty-two of the population. The efforts made at repression were pitifully unequal. In the district of Kensington, covering 15 sq. m., the protection afforded was dependent on three constables and three head-boroughs. In the parish of Tottenham nineteen attempts at burglary were made in six weeks, and sixteen were entirely successful. In Spitalfields gangs of thieves stood at the street door and openly rilled all who came near. In other parishes there was no police whatever, no defence, no protection afforded to the community but the voluntary exertions of individuals and "the honesty of the thieves." In those days victims of robberies constantly compounded with felons and paid blackmail to thieves, promising not to prosecute on the restitution of a portion of the stolen property.

The crying need for reform and the introduction of a proper police was admitted by the government in 1829, when Sir Robert Peel laid the foundation of a better system. Much opposition was offered to the scheme, which was denounced as an insidious attempt to enslave the people by arbitrary and tyrannical methods. The new police were to be employed, it was said, as the instruments of a standing army of disciplined members of a new standing army, under the centralized authority, riding roughshod over the peaceable citizens. But the guardians of order, under the judicious guidance of such sensible chiefs as Colonel Rowan and Sir Henry Maine, soon lived down the hostility first exhibited, and although one serious and lamentable collision occurred between the mob and the police in 1833, it was agreed two years later that the unfavourable impression at one time existing against the new police was rapidly diminishing, and that it had fully answered the purpose for which it was formed.

Crime had already diminished; it was calculated that the annual losses inflicted on the public by the depredations of the dangerous classes had appreciably fallen and a larger number of convictions had been secured.

The formation of the metropolitan police was in due course followed by the extension of the principle to the provinces. Borough constabulary forces were established by the Municipal Corporation Act (1835), which entrusted their administration to the mayor and a watch committee, and this act was revised in 1882, when the general powers of this authority were defined. Acts of 1839 and 1840 permitted the formation by the justices of a paid county police force. Action in this case was optional, but after an interval of fifteen years the Police Act of 1856 made the rule compulsory, it being found that an efficient police force throughout England and Wales was necessary for the more effectual prevention and detection of crime, the suppression of vagrancy and the maintenance of good order. Local acts had already endowed Scotland with a police system, and in 1857, and again in 1862, counties were formed into police districts, and the police of towns and populous places was generally regulated. Ireland has two police forces; the Dublin metropolitan police originated in 1808, and in 1829 the provisions of Sir Robert Peel's act for London were embodied in the Police Law for Ireland.

The extent to which the metropolitan police has developed will best be realized by comparing its numbers on first creation and the nature of the duties and functions that then appertained to it. In the first act, the Metropolitan Police Act of 1829, the act was passed for the better government of the city and borough of Westminster, and this act was re-enacted with extended powers in 1737 and soon succeeded by another (1777) with wider and stricter provisions. The state of London at that date, and indeed of the whole country at large, was deplorable. Crime was rampant, highwaymen terrorized the...
POLICE

The state employs police solely in the interests of the public welfare. No sort of espionage is attempted, no effort made to penetrate privacy; no claim to pry into the secret actions of law-obling persons is or would be tolerated; the agents of authority must not seek information by underhand or unworthy means. In other countries the police system has worked more arbitrarily; it has been used to check free speech, to interfere with the right of public meetings, and condemn the expression of opinion hostile to or critical of the ruling powers. An all-powerful police, minutely organized, has in some foreign states grown into a terrible engine of oppression and made daily life nearly intolerable. In England the people are free to think and they pleasure in marching in procession through the streets, to gather in open spaces, to express what is often forcibly expressed, of mob orators, provided always that no obstruction is caused or that no disorder or breach of the peace is threatened.

The strength of the metropolitan police in 1908 was 18,167, comprising 32 superintendents, 572 inspectors, 2,378 sergeants and 15,185 constables. At the head is a commissioner, appointed by the Home Office, being assisted by four assistant commissioners, of whom one was appointed under the Police Act 1900, in accordance with the recommendation of the Royal Commission on the Metropolitan Police 1906, his duty especially being to deal with the more serious breaches of the public law. Among the assistant commissioners are two divisions, to the divisional superintendents, by way of comparison, have been appointed under the Act 1899, the Metropolitan Police Act.

The metropolitan police district was extended to 15 m. from Charing Cross. The whole of the river Thames (which, in its course through London, so far as related to police matters, had been managed under distinct acts) was brought within its jurisdiction, the powers of the old police being confined to the area of the city proper. The powers of the police were extended to the area of London and the powers of the metropolitan police were extended to the whole of the greater part of the area of the metropolitan police district, as extended by the Metropolitan Police Act, 1900.
suppressed cases are very great. As regards the rural police of India every village headman and his attendants be numerically required by the code to communicate to the nearest magistrate or the officer in charge of the nearest police station, whichever is nearest, any information respecting crimes or disorderly conduct in the system of duties which has numerous duties over and above those of the prevention and detection of crime, greatly aids a government so paternal as that of India in keeping touch with the widely extended masses of the people.

France.—It is a matter of history that under Louis XIV., who created the police of Paris, and in succeeding times, the most popular and unjustifiable use was made of police as a secret instrument. The term police, first adopted in France, was applied to himself largely to police instruments, especially through his minister Foucâât. On the restoration of constitutional government under Louis Philippe, police action was thus dangerous, but the danger reversed itself under the Empire. The history of the police, according to the act of the Directory in 1796, was in 1818 suppressed as an independent office, and in 1852 it was united with the ministry of the interior. The aggrandizement of the office, which ever since the order of 1818 has evaded doing, and runs in “malefactors, falls naturally and broadly into two grand divisions, the administrative and the active, the police in the office and the police “out of doors.” The first attends to the clerical business, voluminous and incessant. An army of clerks in the numerous bureaus, hundreds of patient government employees, the ronds de laur, as they are contemptuously called, because they sit for hours on round leather cushions, are engaged in writing and filling in papers, to be handed from bureau to bureau day after day. The active army of police out of doors, which constitutes the second half of the whole machine, is divided into two classes: that in uniform and that in plain clothes. Every active police officer, from the brigadier down to the private foot-bloody-piece, in his short frock-coat or cape, smart képi cocked on one side of his head, and with a sword by his side. The first is known by the title of agent, sergent de police in the dauphine, and is a very useful police officer. He is almost invariably an old soldier, a sergeant, who has left the army with a first-class character, honesty and sobriety being indispensable qualifications.

These uniformed police are not all employed in the streets and arrondissements, but there is a large reserve composed of the six central brigades, as they are called, a very smart body of old soldiers, well drilled, well dressed and fully equipped; armed, moreover, with revolvers which they carry, quite often as portmanteaux, at the doors or entrance of the prefecture. In Paris argot the men of these six central brigades are nicknamed “vaisseliers” (vessels), because they carry on their collars the badge of the city of Paris—an ancient ship—while the servants in the towns district wear only numbers, their own individual number, and that of the quarter in which they serve. These vaisseliers claim to be the élite of the force; they come in daily contact with the Gardes de la paix, who are of a fine class of men, and who are so competing with them, take a particular pride in themselves. Their comrades in the quarters resent this pretension and declare that while in contact with the gardes de la paix, they are only their equals and want of tact. The principal business of four of these central brigades is to be on call when required to reinforce the out-of-door police at special times.

Of the central brigades, the chief one controls public carriages, the other the Hailes, the great central market by which Paris is provided with a large part of its food. Every cab-stand is under the charge of its own policeman, who knows the men, notes their arrival and departure, and has a special rapport with the cabs. The few police officers of the central brigades superintend the street traffic.

So much for the police in uniform. The, in plain clothes, en bourgeois, as the French call it, is not so numerous, but fulfills a higher, or at least a more confidential mission. Its members are styled inspectors, not agents, and their functions fall under four principal heads. There is, first of all, the service of the Sûreté—in France the police are divided into two classes, the administrative and the active, the Sûreté being the administrative organ. It is employed entirely in the pursuit and capture of criminals; next comes the police, now amalgamated with the Sûreté, that watches over the town, the details of personal and property claims under the existing laws of France; then there is the brigade de garnis, the police charged with the supervision of all lodging-houses, from the commonest shopkeepers’ shops, as it is called, to the grandest house of the great variety of private houses, whose business it is to act as the eyes and ears of the prefecture.

The pay of the gardiens de la paix is from 1400 to 1700 francs; brigadiers get 2000 francs; sous-brigadiers 1600 francs; officiers de paix 3000 francs. The proportion of police to inhabitants is one in 352.

Germany.—Taking the Berlin force as illustrative of the police system in the German Empire, police duties are as various as in France. Berlin has a political and administrative police under the superintendence of an officer of cabinet rank, responsible to the government ministry, who has charge of all departmental matters. There is a special police force under the same head, responsible to the government ministry, who has charge of all departmental matters. Police duties are carried out under the direction of the royal police president, the executive force comprising a police colonel, with, besides commissaries of criminal investigations, captains, lieutenants, acting-lieutenants, sergeant-major and a large body of other commissioned and non-commissioned officers.

It is computed that the proportion of population to police in Berlin is between 350 and 400 to each officer. The pay of the police is principally provided from fiscal sources and varies in an ascending scale, according to a scale of 1145 marks and lodging allowance for the lowest class of constable.

Austria.—Taking Vienna in the same way as illustrative of the Austrian police, it is observed that there are three branches: (1) the police de surveillance, or the police for safety; (2) the police for information; (3) the police of the interior. The head of the government branch sometimes fills the office of universal inspector. Each of the branches is subdivided into departments, at the head of which are Polizeirathes. Passing over the subdivisions of the administrative branch, the police department includes the following departments: the office for public safety, the central inquiry office and the record or Evidenzbureau. The government police branch comprises three departments: the government police of the interior, the police of the burgomasters, with assistant commissaries, and the police of the municipalities. The proportion of police to inhabitants is one to 436.

Belgium.—In Belgian municipalities the burgomasters are the heads of the force, which is under their control. The administrator of public safety is, however, specially under the minister of justice, who sees that the laws and regulations affecting the police are properly carried out, and he can call on all public functionaries to act with the police. The police of the interior is charged with the safety is charged with the administration of the law in regard to aliens, and this law is applied to persons stirring up sedition. The duty of the police is, in the case of horse and foot police, generally to maintain internal order. In large cities as Berlin and Brussels, as elsewhere, the burgomaster is the head, but for executive purposes there is a chief commissary (subject, however, to the orders of the burgomaster), with assistants and assistant commissaries of divisions and other officers and central and other bureaus, with a body of agents (police constables) in each.

There are two main classes of police functions recognized by law in the administrative and the judicial police, the former engaged in the daily maintenance of peace and order and so preventing offences, the latter in the investigation of crime and tracing offenders; but the duties are necessarily performed to a great extent by the same class of force. The police is, however, limited to the same classes of officers, and they perform the same duties as in Paris—the law in practice being expressly adopted in Brussels.

In Switzerland, which is sometimes classed with Belgium as among the least-policied states of Europe, the laws of the cantons vary. In some respects they are stricter than in Belgium or even in France. Thus a permissâ de séjou is sometimes required where one police. Practically, Russia was till lately the most police-ridden country in the world; not even in France in the worst days of the monarchy were the people so controlled, and no people have ever been more strictly watched than those by the reachings of the police, the power assumed in matters momentous and quite insignificant, we may quote from the list of circulars issued by the minister of the interior to the governors of the four provinces of Russia: (1) regulations for the police were directed to regulate religious instruction in secular schools, to prevent horse-stealing, to control subscriptions collected for the holy places in Palestine, to regulate the advertisements of medicines and the printing, etc., of the press, to examine the quality of quinine soap and overlook the cosmetics and other toilet articles—such as soap, starch, brilliantine, tooth-brushes and insect-powder—provided by chemists. They were to issue regulations for the proper construction of houses and villages, to exercise an active censorship over published price-lists and printed notes of invitation and visiting cards, as well as seals and rubber stamps. All private meetings and public gatherings, with the expressions of opinion and the class of subjects discussed, were to be approved by the police.

The political or state police was the invention of Nicholas I. Alexander I. had an inspector-general of police, but it was Nicholas who devised the second branch, which he designed for his own protection and the security of the state. After the insurrection of 1865, he created a special body of police, and restructured the administration of police affairs. Three Sections” of the emperor’s own chancery, and while it lasted, was the most dreaded power in the empire. It was practically supreme in the state, a ministry independent of all other ministries, placed quite above them and responsible only to the tsar himself.

United States.—The organization of police forces in the United States differs more or less in the different states of the Union. As a rule the police of the cities is not divided into a political and administrative branch, but there are numerous exceptions. In Boston, for instance, the three commissioners at the head of the force are appointed by the governor of Massachusetts. The force in New York City, alike from the standpoint of numbers and of the size and character
of the city, is the most important in the United States. It included in 1910 a commissioner appointed by the mayor and exercising a wide range of authority; four deputy commissioners; a chief inspector; and a force of 500 men, the total number of all orders is issued; he is assisted by 18 inspectors, who are in charge of different sections of the city, and who carry out the orders of the chief; 87 captains, each of whom is in direct charge of about 20 men, and lastly the patrolmen, or patrolmen, as they are often called from the character of their duties. There is a separate branch, the detective bureau, composed of picked men, charged with the investigation and, still more, the prosecution of major acts. The number of patrolmen in 1901 was 8562. Appointments are for life, with pensions in case of disability and after a given number of years of service.

LITERATURE.—Patrick Colquhoun, Treatise on the Police of the Monarchy, and its subsequent continuation under Louis XIV. (1860); Maxime Du Camp, Paris, ses organes, ses fonctions et sa vie (1869-1875); Dr Norman Chevers, Indian Medical Jurisprudence (Calkuta, 1870); A. T. Crawford, Reminiscences of an Indian Police Official (1894); C. R. W. Hervey, Records of Indian Crime, 1601-1903; Arthur Griffiths, Mysteries of Police and Crime (1903); Captain W. L. Melville Lee, A History of Police in England (Methuen, 1901); Sidney and Beatrice Webb, English Local Government (Longmans, 1906-1908); Political and Judicial History of the Metropolitan Police District, in the English Historical Review (October 1895); F. W. Maitland, Justice and Police (Macmillan, 1885); L. F. Fuld, Police Administration (New York, 1910).

POLICE COURTS, courts of summary jurisdiction, held in London and certain large towns of the United Kingdom by specially appointed and salaried magistrates. They were originally called "public offices" (Middlesex Justices Act 1792), but after the establishment of the police force, in 1829, they came to be called "police offices," the change having taken place in their nature. They are so described in a report of a select committee which inquired into the system in 1837 and 1838; in the same report the magistrates who presided in the courts were first described as "police magistrates." Police offices were first officially described by their modern title in the Metropolitan Police Courts Act 1839. In 1839 there were nine police courts; since 1792 there had been three magistrates to each court, and the act of 1839 retained twenty-seven as the maximum number at any time (s. 2). In 1833 unsalaried justices ceased to sit in the police courts along with the paid magistrates. The Metropolitan Police Courts Act 1840 gave power to the Lord Mayor of London to divide the police districts into police court divisions, and to establish police courts wherever necessary, the artificial limit of twenty-seven magistrates being at the same time preserved. Additional courts have from time to time been established by orders in council, and in 1910 there were in London fourteen courts with twenty-five magistrates. Their divisions are regulated by orders in council of 1903 and 1905; the nine original courts are Bow Street, Westminster, Marylebone, Marlborough Street, Worship Street, Clerkenwell, Thames, Tower Bridge and Lambeth.

The courts are held every day from 10 a.m. to 5 p.m. except on Sunday, Christmas Day, Good Friday or any day appointed for a public fast or thanksgiving or bank holiday. The Green Park and Woolwich court, which comprises one division, is held at Greenwich in the morning and at Woolwich in the afternoon. The chief magistrate (sitting at Bow Street) receives a salary of £1800 a year, plus £1000 each for the other thirty magistrates appointed by the Crown; they must have been practising barristers for seven years or stipendiary magistrates for some place in England or Wales. One police magistrate has the same powers as a justice of the peace, and he has to do at special or petty sessions of all the justices acting in the division or at quarterly sessions. He can do alone when sitting in a police court act which any justice of the peace under the Summary Jurisdiction Act 1846, or under the Summary Jurisdiction Act; he has special powers under the Metropolitan Police Courts Act 1839, and is also given special powers under certain other acts. The Bow Street magistrates exercise the traditional custom of appointing salaried magistrates was followed for certain towns in the provinces by particular acts, and in 1863 the Stipendiary Magistrates Act gave power to towns and boroughs of 25,000 inhabitants and upwards to obtain a stipendiary magistrate.

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute Loire). Its authentic pedigree can be traced to the 9th century, but in 1421 the male line became extinct. The heiress married Guillaume, sire de Chalanon (not to be confused with the barons of Chalanon in Vivarais), who assumed the name and arms of Polignac. The first member of the family who was of any historical importance was Cardinal Melchior de Polignac (1661-1742), a younger son of Armand XVI., marquis de Polignac, who at an early age achieved distinction as a diplomatist. In 1695 he was sent as ambassador to Poland, where he contrived to bring about the election of the prince of Conti as successor to John Sobieski (1697). The subsequent failure of this intrigue led to his temporary disgrace; but in 1702 he was restored to favour, and in 1712 he was sent as the plenipotentiary of Louis XIV. to the Congress of Utrecht, and during the next ten years he became involved in the Cellamare plot, and was relegated to Flanders for three years. From 1725 to 1732 he acted for France at the Vatican. In 1726 he received the archbishopric of Auch, and he died at Paris in 1742. He left unfinished a metrical retutation of Lucretius which was published after his death by the abbé de Rothelin (Anti-Lucretius, 1743), and had considerable vogue in its day. Count Jules de Polignac (d. 1817), grandnephew of the preceding, was created duke by Louis XVI. in 1780, and in 1782 was made postmaster-general. His position and influence at court were largely due to his wife, Gabrielle de Polastron, the bosom friend of Marie Antoinette; the duke and duchess contrived the summit of the court, and the latter was the first to "emigrate" in 1790. The duchess died shortly after the queen, but her husband, who had received an estate from Catherine II. in the Ukraine, survived till 1817. Of their three sons the second, Prince Jules de Polignac (1780-1847), played a conspicuous part in the clerical and ultra-royalist reaction after the Revolution. Under the empire he was implicated in the conspiracy of Cadoudal and Pichegru (1804), and was imprisoned till 1813. After the restoration of the Bourbons he held various offices, received from the pope his title of "prince" in 1830, and in 1823 was made ambassador to the English court. On the 8th of August 1829 he was called by Charles X. to the ministry of foreign affairs, and in the following November he became president of the council. His appointment was taken as symbolical of the king's intention to overthrow the constitution, and Polignac, with the other ministers, was held responsible for the policy which culminated in the issue of the Four Ordinances which were the immediate cause of the revolution of July 1830. On the outbreak of this he fled for his life, but, after wandering for some time among the wilds of Normandy, was arrested at Granville. His trial before the chamber of peers resulted in his condemnation to perpetual imprisonment (at Ham), but he benefited by the amnesty of 1836, when the sentence was commuted to exile, and, under the terms of the amnesty he wrote Considerations politiques (1831). He afterwards spent some years in England, but finally was permitted to re-enter France on condition that he did not take up his abode in Paris. He died at St Germain on the 29th of March 1847.

POLIGNY, a town of eastern France, capital of an arrondissement in the department of Jura, 18 m. N.W. of Lons-le-Saunier on the Paris-Lyon railway. Pop. (1906), 3756. The town lies in the valley of the Glantine at the base of a hill crowned by the ruins of the old castle of Grimont, once the repository of the archives of the county of Burgundy. The church of Montivillar, its most remarkable building, dates from the 12th century, its chief features being a Romanesque tower and reroles of the Renaissance period. Amongst the other old buildings of the town, the church of St Hippolyte, of the first half of the 15th century, and a convent-church serving as corn market are of some interest. The tribunal of first instance belonging to the arrondissement is at Arbois. Poligny has a sub-prefecture, a communal college and a school of daily instruction. Under the name of Poletiumacum the town seems to have existed at the time of the Roman occupation.

POLISH SUCCESSION WAR (1733-1735), the name given to a war which arose out of the competition for the throne of Poland between the elector August of Saxony, son of August II. (the Strong), and Stanislaus Leszcynski, the king of Poland installed thirty years before by Charles XII. of Sweden, and displaced by
August the Strong when Charles's projects collapsed. The claims of Stanislaus were supported by France, Spain and Sardinia, those of the Saxony prince by Russia and the empire, the local quarrel being made the pretext for the settlement of minor outstanding claims of the great powers amongst themselves. The war was therefore a typical 18th century "war with a limited object," in which no one but the cabinets and the professional armies were concerned. It was fought on two theatres, the Rhine and Italy. The Rhine campaigns were entirely unimportant, and are remembered only for the last appearance in the field of Prince Eugène and Marshal Berwick—the latter was killed at the siege of Phillippsburg—and the baptism of fire of the young crown prince of Prussia, afterwards Frederick the Great. In Italy, however, there were three hard-fought—though indecisive—battles, Parma (June 29, 1734), Luzzara (Sept. 19, 1734) and Bitonto (May 25, 1735), the first and last won by the Austrians, the second by the French and their allies. In Poland itself, Stanislaus, elected king in September 1733, was soon expelled by a Russian army and was afterwards besieged in Danzig by the Russians and Saxons (Feb.–June 1733).

POLITIAN (1454–1494). Angelo Ambrogini, known in literary annals as Angelo Poliziano or Polizianus from his birthplace, was born at Pistoia, Tuscany, on 14.11.1454. His father, Benedetto, a jurisconsult, a good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano; and this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten the boy came to prosecute his studies at Florence, where he learned Latin under Cristoforo Landino, and Greek under Argyropoulos and Andronicos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. The precocity of his genius for scholarship and poetry was early manifest. At thirteen years of age he began to circulate Latin letters; at seventeen he sent forth essays in Greek versification; at eighteen he published an edition of Catullus. In 1470 he won for himself the title of Homerius juvenis by translating four books of the Iliad into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household, made him the tutor of his children, and secured him a distinguished post in the university of Florence. Before he reached the age of thirty, Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the epistola opinia of Italian culture. Not to mention Italy kills. In 1482 de' Medici was exiled by the Germans, Reuchlin, the English Grocyn and Linacre, and the Portuguese Tiresius.

Poliziano had few advantages of person to recommend him. He was ungainly in form, with eyes that squinted, and a nose of disproportionately length. Yet his voice was rich and capable of fine modulation; his eloquence, ease of utterance and copious stream of erudition were incomparable. It was the method of professors at that period to read the Greek and Latin authors with their class, dictating philological and critical notes, emitting corrupt passages in the received texts, offering elucidations of the matter, and pouring forth stores of acquired knowledge regarding the laws, manners, religious and philosophical opinions of the ancients. Poliziano covered nearly the whole ground of classical literature during the years of his professorship, and published the notes of his courses upon Ovid, Suetonius, Statius, the younger Pliny, Quintilian, and the writers of Augustan histories. He also undertook a recension of the text of the Pandects of Justinian, which formed the subject of one of his courses; and this recension, though it does not rank high in the scale of juristic erudition, gave an impulse to the scholarly criticism of the Roman code. At the same time he was busy as a translator from the Greek. His versions of Epictetus, Herodotus, Demosthenes, Galen, the Church's Erotics and Plato's Charmides delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labours the most universally acceptable to the public of that time were a series of discursive essays on philology and criticism, first published in 1489 under the title of Miscellanea. They had an immediate, a lasting and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however, contented with these simply professional and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of Latin and Greek verses, with much among the best of these produced by men of modern times in rivalry with ancient authors. The Manto, in which he pronounced a panegyric of Virgil; the Ambra, which contains a beautiful idyllic sketch of Tuscan landscape, and a studied eulogy of Homer; the Rutilius, which celebrated the pleasures of country life in no frigid or scholastic spirit; and the Nutricia, which was intended to serve as a general introduction to the study of ancient and modern poetry—these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling, and a command of metrical resources which mark them out as original productions of poetic genius rather than as purely professional labors. Exception need not be taken to their conclusion being a little cold with the East, the sort of the Augustan or even of the Silver age. But what renders them always noteworthy to the student of modern humanistic literature is that they are in no sense imitative or conventional, but that they convey the genuine thoughts and emotions of a born poet in Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano was great as a scholar, as a professor, as a critic, and as a Latin poet at an age when the classics were still studied with the passion of assimilative curiosity, and not with the scientific industry of a later period. He was the representative hero of that age of scholarship in which students drew their ideal of life from antiquity and fondly dreamed that they might so restore the past as to compete with the classics in production and bequeath a golden age of resuscitated paganism to the modern world. Yet he was even greater as an Italian poet. Between Boccaccio and Ariosto, no single poet in the mother tongue of Italy deserves so high a place as Poliziano. What he might have achieved in this department of literature had he lived at a period less preoccupied with humanistic studies, and had he found a congenial sphere for this activity, can only be guessed. As it is, we must reckon him as decidedly the foremost and indubitably the most highly gifted among the Italian poets who, during the 16th century, stood so high in the demand of his contemporaries. La Giostra had no plan, and remained imperfect; but it demonstrated the capacity of the octavestanza for rich, harmonious and sonorous metrical effect. The Orfeo is a slight piece of work, thrown off at a heat, yet abounding in an inexpressible lyriel beauty, and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "rousing fluency," an exquisite charm of half romantic, half humorous abandon to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engraven on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity and natural flow of language.

It is difficult to combine in one view the several aspects presented to us by this many-sided man of literary genius. At
a period when humanism took the lead in forming Italian character and giving tone to European culture, he climbed with facility to the height of achievement in all the branches of scholarship which were then most seriously prized—in varied knowledge of ancient authors, in critical capacity, in rhetorical and poetical exuberance. This was enough at that epoch to direct the attention of all the learned men of Europe on Poliziano. At the same time, almost against his own inclination, certainly with very little enthusiasm on his part, he lent himself so successfully to Lorenzo de' Medici's scheme for resuscitating the decayed literature of Tuscan that his slightest Italian excursions exercised a potent influence on the immediate future. He appears before us as the dictator of Italian culture in a double capacity—as the man who most perfectly expressed the Italian conception of humanism, and brought erudition into accord with the pursuit of noble and harmonious form, and also as the man whose vernacular compositions were more significant than any others of the great revolution in favour of Italian poetry which culminated in Ariosto. Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of the part he took in a curious document on the death of Lorenzo de' Medici to the students of Florentine history. But he was not, like many other humanists of his age, concerned in public affairs of state or diplomacy, and he held no office except that of professor at Florence. His private life was also uneventful. He passed it as a house-friend and dependant of the Medici, as the idol of the learned world, and as a simple man of letters for whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a certain amount of plausible colouring. In character Poliziano was declared to have wanted the intellectual qualities in which he displayed. He died, half broken-hearted by the loss of his friend and patron Lorenzo de' Medici, on the 24th of September 1494, just before the wave of foreign invasion which was gathering in France swept over Italy.

For the life and works of Poliziano, see F. O. Mencken (Leipzig, 1736), a vast repertory of accumulated erudition; Jac. Mählly, Angelus Politianus (Leipzig, 1864); Carducci's edition of the Italian poems (Florence, Barbera, 1865); Del Lungo's edition of the Italian prose works and Latin and Greek poems (Florence, Barbera, 1867); the Opera omnia (Basel, 1554); Gresswell's English Life of Polizianus (1865); Roscoe's Lorenzo de Medici (10th ed., 1863); Bancroft's History of the Italian Renaissance in Italy, and selections from Poliziano's Italian poems in Symonds's Sketches and Studies in Italy, which include the Orfeo.

POLK, JAMES KNOX (1795-1849), eleventh president of the United States, was born in Mecklenburg county, North Carolina, on the 2nd of November 1795. In 1806 he crossed the mountains with his parents and settled in what is now Maury county, Tennessee. He graduated from the university of North Carolina in 1818, studied law in the office of Felix Grundy (1777-1846) at Nashville in 1819-1820, was admitted to the bar in 1820, and began to practise in Columbia, the county-seat of Maury county. After two years of service (1823-1825) in the state House of Representatives, he represented the sixth Tennessee district in the National House of Representatives from 1825 to 1839. In the party conflicts which succeeded the presidential election of 1824 he sided with the Jackson-Van Buren faction, and soon became recognized as leader of the Democratic forces. He was speaker from 1835 until 1839, when he retired from Congress to become governor of Tennessee. His administration (1830-1841) was successful, but he was unable to overcome the popular Whig movement of that period, and was defeated in 1841 and again in 1843. When the Democratic national convention met in Baltimore in 1844 he was mentioned as a possible candidate for the vice-presidency, but was suddenly brought forward as a "dark horse" and selected to be the ticket. Finding it impossible under the two-thirds rule to nominate their candidate, the followers of Van Buren brought forward Polk, who was popular in the South, in order to defeat Lewis Cass and James Buchanan. George Bancroft, the historian, has asserted that this suggestion came originally from him, and Gideon J. Pillow, Polk's intimate friend, did much to bring about the nomination.

The unequivocal stand of Polk and his party in favour of the immediate annexation of Texas and the adoption of a vigorous policy in Oregon contrasted favourably with the timid vacillations of Henry Clay and the Whigs. Polk was elected, receiving 170 electoral votes to 105 for his opponent Clay. In forming his cabinet he secured the services of James Buchanan of Pennsylvania, as secretary of state, Robert J. Walker of Mississippi, as secretary of the treasury, William L. Marcy of New York, as secretary of war, and George Bancroft, then of Massachusetts, as secretary of the navy. There is no doubt that each of these men, and Bancroft in particular, influenced the policy of the administration, yet the historian James Schouler, who has made a careful study of the Polk papers, is doubtless correct in saying that the president himself was the "framer of the public policy which he carried into so successful execution, and that instead of being led (as many might have imagined) by the more famous statesmen of his administration and party who surrounded him, he in reality led and shaped his own executive course." Bancroft's opinion is that Polk was "prudent, fast-sighted, bold, exceeding any Democrat of his day in his unutterably correct exposition of Democratic principles."

The four chief events of President Polk's administration were the final establishment of the independent treasury system, the reduction of the tariff by the Walker Bill of 1846, the adjustment of the Oregon boundary dispute with Great Britain by the treaty concluded on the 15th of June 1846, and the war with Mexico and the consequent acquisition of territory in the south-west and west. The first three of these were recommended in his first annual message, and he privately announced to Bancroft his determination to seize California. The independent treasury plan originated during Van Buren's administration as a Democratic measure; it had been repealed by the Whigs in 1841, and was now re-enacted. Protectionists contend that the tariff legislation of 1845 was in direct violation of a pledge given to the Democrats of Pennsylvania in a letter written by Polk during the campaign to John K. Kane of Philadelphia. Briefly summarized, this letter approves of a tariff for revenue with incidental protection, whereas the annual message of the 1st of December 1845 criticizes the whole theory of protection and urges the adoption of a revenue tariff just sufficient to meet the needs of the government conducted on an economical basis.

The treaty which led to the acquisition of Oregon was not of incidental protection, or whether his views were changed after 1844 through the influence of Walker and the example set by Sir Robert Peel in Great Britain, or whether he was simply "playing politics" to secure the protectionist vote in Pennsylvania.

The one overshadowing issue of the time, however, was territorial expansion. Polk was an ardent expansionist, but the old idea that his policy was determined entirely by a desire to advance the interests of slavery is no longer accepted. As a matter of fact, he was personally in favour of insisting upon 54° 40' as the boundary in Oregon, and threw upon Congress the responsibility for accepting 49° as the boundary, and he approved the acquisition of California, Utah and New Mexico, territory from which slavery was excluded by geographical and climatic conditions. Furthermore a study of his manuscript diary now shows that he opposed the efforts of Walker and Buchanan in the Cabinet, and of Daniel S. Dickinson (1800-1866) of New York and Edward A. Hannegan (d. 1859) of Indiana, in the Senate, to retain the whole of Mexico, territory in which slavery might have thrived. At the close of his term (March 4, 1849) Polk retired to his home in Nashville, Tennessee, where he died on the 15th of the following June.

1 Bancroft served until September 1846, when he was appointed minister to England. He was succeeded as secretary of the navy by John J. Mason, who had previously held the office of attorney-general.
POLK, L.—POLKA

See John S. Jenkins, *James Knox Polk* (Auburn and Buffalo, 1850), and L. B. Chase, *History of the Polk Administration* (New York, 1850), both of which contain some documentary material, but are not discriminating in their method of treatment. George Bancroft contributed a good short sketch to J. G. Wilson's *Presidents of the United States* (New York, 2nd ed., 1864). He made copies of the Polk manuscripts and was working upon a detailed biography at the time of his death in 1891. These copies, now deposited in the Lenox Library, New York City, contain a diary in 24 typewritten volumes, besides some correspondence and other private papers. They have been used by James Schouler in his *Historical Briefs* (New York, 1896), and by E. G. Bourne in an article entitled "The Proposed Absorption of Mexico in 1847-1848," published in the *Annual Report of the American Historical Association for 1899*, i. 157-169 (Washington, 1900). Bourne discusses the part which Polk took in preventing the complete absorption of Mexico. See also the *Diary of James K. Polk . . . . 1845 to 1849* (Chicago, 4 vols., 1910), edited by M. M. Quaife.

(W. R. S.*)

**POLK, LEONIDAS** (1806-1864), American soldier, was born at Raleigh, North Carolina, on the 10th of April 1806, and was a cousin of James Knox Polk, president of the United States. He was educated at West Point, but afterwards studied theology and took orders in the Protestant Episcopal Church in 1831. In 1838 he became missionary bishop of the South-West, Arkansas, Indian Territory, Louisiana, Alabama and Mississippi, and in 1841 he was consecrated bishop of Louisiana. His work in the Church was largely of an educational kind, and he played a prominent part in movements for the establishment of higher educational institutions in the South. At the outbreak of the Civil War in 1861 he resigned his bishopric and, like many other clergymen and ministers of religion, entered the army which was raised to defend the Confederacy. His rank in the hierarchy and the universal respect in which he was held in the South, rather than his early military education, caused him to be appointed to the important rank of major-general. He fortified the post of Columbus, Kentucky, the foremost line of defence on the Mississippi, against which Brigadier-General U. S. Grant directed the offensive reconnaissance of Belmont in the autumn. In the following spring, the first line of defence having fallen, Polk commanded a corps at Shiloh in the field army commanded by Albert Sidney Johnston and Beauregard. In October 1862 he was promoted lieutenant-general, and thenceforward he commanded one of the three corps of the army of Tennessee under Bragg and afterwards was in charge of the Department of Alabama, Mississippi and East Louisiana. He was killed in the fighting in front of Marietta, while reconnoitring near Pine Mountain, Georgia, on the 14th of June 1864.

See *Life*, by his son W. M. Polk, (1893).

**POLKA** (either from the Czech *pulka*, half, with an allusion to the short steps characteristic of the dance, or from the Polish *polka*, feminine of *Polsk*, a Pole), a lively dance of Bohemian origin, danced to music written in 3 time. (See DANCE.)
